# How to read this manual

Every screen gets its own section, always in the same order: a real capture of the application, what it is for, a walk down the screen, what each figure means, how to do the concrete things, and finally what tends to confuse people. Read it through, or open it only at the screen in front of you.

## The four signals

The whole application turns on a single piece of arithmetic: how many days you last with what you hold, against how long your supplier takes to deliver. Four signals come out of it, and you will see them on almost every screen.

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| <b>PEDIR_YA</b>     | You run out before the next order arrives.                          |
| <b>PEDIR_PRONTO</b> | Not urgent yet, but it will be if you wait until next week.         |
| <b>OK</b>           | You have enough coverage. Nothing to decide today.                  |
| <b>SOBRE STOCK</b>  | You hold far more than you will sell: that is money standing still. |

# Getting started and your account

This chapter covers two things. The first is the whole path a new user walks: creating the account, uploading the first sales file, filling in the inventory and reading the first traffic light. The second is the five screens where you administer the account itself: Users, My account, Automation, API and Installation. None of those five is needed on day one, but they are the ones you decide once and then barely touch again.

## Getting started

### WHAT IT IS FOR

StockAI guesses nothing about your business: it learns from your sales history and compares that forecast against what you hold in the warehouse. That is why the start has a fixed order — first your sales, then your inventory, and only then the traffic light. This walk is what decides whether the product works for you, and you do it once.

### WALKING THE SCREEN

1. Go to the StockAI landing page and create your account: the “Create your workspace” form asks for your full name, company name, email address, WhatsApp and a password, and the password has to meet the four conditions you see tick off live — 8 characters, one uppercase letter, one number and one symbol.
2. The WhatsApp number is not filler: it is where your purchase orders arrive so you can forward them to your suppliers, so write it with the country code, for example +50688887777.
3. When you submit the form you will see “Check your email”: we send a verification link, and opening it activates your account so you can sign in.
4. You can sign in and work before verifying — uploading the file, training and seeing the traffic light all work; what stays blocked until you verify are the actions that leave your company: inviting people and sending notifications.
5. Signing in lands you on the Purchasing Panel, which on an empty account says “You don’t have data yet” and offers two ways forward: “Upload my sales history” and “Try it with demo data”, which loads sample sales for 5 products and never touches your data.
6. The first button takes you to My sales, which works in three numbered steps: “Upload your sales”, “Confirm columns” and “The system learns”.
7. Before dropping the file, fill in the four fields at the top: a name for the run (optional), how far ahead you want to plan, the plan detail level, and which country you sell in — we use that last one for public holidays, which are among the days that move sales the most and differ in every country.
8. Drag your file in or click to pick it: we accept CSV and Excel (.xlsx, .xls), and it must carry at least three columns — date, product and quantity sold.
9. In “Confirm your columns” you tell us which column is the date, which is the quantity sold and which is the product; pick the product column even if you carry a single product, because leaving it as “a single product” merges everything into one series and you lose the per-product detail.
10. If the file carries problems that would produce a wrong forecast, the screen makes you resolve them before continuing and each option states what it does and what it costs; the warnings that do not block are simply reported.

11. Training runs on its own and can take several minutes depending on the size of your file: do not close the tab, and when it finishes we take you to the traffic light with the daily view ready while the rest keeps computing in the background.

12. Now open “Set up inventory” and fill in the three things StockAI still does not know about each product: how many units you hold today, what one unit costs you, and how many days your supplier takes to deliver.

13. That list is not alphabetical but ordered by money, and it tells you at the top how many products you need to complete to cover the bulk of this month’s purchase — you do not have to configure them all; if you prefer, upload the stock file exactly as your system exports it.

14. Go back to the Purchasing Panel and read the traffic light — Order NOW, Order soon, OK, Overstock and No data — with the suggested quantity per product, and once you confirm a purchase, record it in Orders: without that record the order does not exist for StockAI and your suppliers’ real lead times are never learned.

#### WHAT EACH FIGURE MEANS

| Field             | What it is                                                                                                         |
|-------------------|--------------------------------------------------------------------------------------------------------------------|
| Date              | The column in your sales file with the date of the sale. It is required.                                           |
| Product / SKU     | The column that identifies each product: a code, a reference or a name. Pick it even if you have a single product. |
| Quantity sold     | The units sold on that date. It has to be a numeric column.                                                        |
| Stock             | How many units you physically hold today, not counting anything in transit. Filled in on Set up inventory.         |
| Cost              | What YOU pay your supplier per unit, not the price you sell it at.                                                 |
| Lead time in days | How many days pass between placing the order with your supplier and the goods being in your warehouse.             |

#### HOW TO

##### Go from zero to your first traffic light with your own file

1. Create the account and open the verification link in your email. 2. Sign in and, on the Purchasing Panel, click “Upload my sales history”. 3. Choose the horizon, the detail level and your country, then upload your sales CSV or Excel. 4. Confirm the date, product and quantity-sold columns. 5. Wait for training to finish without closing the tab. 6. Open “Set up inventory” and fill in stock, cost and lead time for the products the list puts at the top. 7. Go back to the Purchasing Panel: there is your traffic light with the suggested quantity per product.

##### See how it works before your file is ready

1. Sign in. 2. On the Purchasing Panel click “Try it with demo data”. 3. Wait for the load to finish: it drops you straight into the traffic light with 5 sample products. 4. Walk the Purchasing Panel, Inventory and Forecasts with that data. 5. When you have your real file, go back to My sales and upload it: the demo never touches your data.

#### WORTH KNOWING

- A product needs at least 20 periods of history to enter the forecast. The ones that fall short are left out of the calculation: they do not show up with a bad forecast, they simply do not show up.

- Without stock or without cost, a product gets no signal and comes out as “No data”. It is not broken: it is unconfigured.
- Without a lead time the product does appear, but planned on an assumed 15 days. If your supplier takes 45, the warning will reach you late.
- On the free plan each file can be up to 25 MB and the account holds up to 100 products. When you outgrow that, the screen says so and opens the dialog to write to us.
- Do not close the tab while the system is learning. The process can take several minutes depending on the size of your file.

# Daily operation

These four screens are your everyday routine: you open the Purchasing Panel in the morning to decide what to order, go into Inventory when you need to check or fix a particular product, pass through Orders when goods arrive, and use Messages to coordinate with your team without leaving StockAI. The first three work on the same data — the demand forecast and the stock you have on record — so what you fix in one shows up in the others.

## Purchasing Panel

/compras

The screenshot shows the StockAI Purchasing Panel interface. The sidebar on the left contains navigation options: OPERATIONS (Purchasing Panel, Orders, Messages), DATA (My sales), PURCHASING (Inventory, Set up inventory, Suppliers), ANALYSIS (Forecasts, Impact, History, What happened, AI Assistant, Scenarios), and SYSTEM (Users, My account, Automation, Installation, API). The main content area is titled 'Purchasing Dashboard' and includes a greeting 'Good morning, Demo.' with 13 pending actions. It shows a list of orders to arrive, a summary of the current situation, and a list of priority risks.

**Purchasing Dashboard** Your upcoming purchases, calculated.

Good morning, Demo. You have 13 pending action(s) today.

Today is Wednesday, September 30, 2026. Update in use: Demo StockAI

⚙ Sales updated 7 days ago ⬆ Upload new sales

ⓘ This recommendation uses 1 assumption of ours — review it  
You have not given us the service level for 21 of the 21 products on this screen, so we used our own values. See what to configure first →

**DID THESE ORDERS ARRIVE?**

- ⚠ The order to **Distribuidora Andina S.A.** was due 6 day(s) ago — did it arrive? [Record arrival](#)
- ⚠ The order to **Granos del Valle** was due 1 day(s) ago — did it arrive? [Record arrival](#)
- ⚠ The order to **Distribuidora Andina S.A.** was due 0 day(s) ago — did it arrive? [Record arrival](#)

📦 3 orders on the way — have they arrived? [Record arrival →](#)

Products watched: **40** Risk today: **4** This week: **9** Warehouse value: **€202K**

**Executive summary of the day** [Needs attention](#)

**CURRENT SITUATION**  
Of 40 SKUs monitored, 19 are healthy and 4 are at immediate risk of stockout, two of them within 1–2 days. 9 SKUs require an order this week, while 8 are overstocked. Total inventory value is €201,601, of which €74,748 is capital trapped in overstock — roughly 37% of stock value. Average forecast accuracy stands at 87.6%.

**PRIORITY RISKS**

- Harina de Maíz 1kg #34: 1 day of cover left — highest stockout risk today.
- Aceite Vegetal 900ml #24 and Aceite de Oliva 1L: 2 days each; both are core lines for customer fill rate.
- Harina de Trigo 1kg: 3 days, adding a second flour reference to the critical list.

### WHAT IT IS FOR

This is the screen you start the day with. It takes the demand forecast and the stock you have on record and hands you a short list of decisions: which products to order today, which ones can wait until this week, how much of each, and from which supplier. You approve or reject line by line and generate the purchase order at the end.

### WALKING THE SCREEN

1. Top left is the “Purchasing Dashboard” badge with the subtitle “Your upcoming purchases, calculated.”, and below it the greeting with your name and how many actions are pending today.
2. Under the greeting sit the date and “Data in use”, the name of the sales upload everything you see was computed from; on the right, the indicator of how fresh that data is.

3. If your stock or your sales have gone a long time without an update, a notice appears before anything else: the traffic light below was computed on stale data and cannot be presented as trustworthy.
4. The assumptions notice (“These recommendations use N assumptions of ours”) shows up when part of the calculation used values you never gave us, and links to what to configure first.
5. Then come the supplier warnings: suppliers running later than usual, and orders whose arrival date has already passed (“Did these orders arrive?”) with a “Record arrival” button.
6. The indicator row shows Total SKUs monitored, Risk today, This week, Average accuracy and Warehouse value, with a note underneath when some products have no stock count.
7. “Executive summary of the day” is a paragraph explaining the situation in words; it has a button to generate it again.
8. If you have more than one warehouse, transfer suggestions appear before the purchases: moving stock between your own warehouses is free, so it is proposed before buying.
9. “Urgent — act today” lists the products with the PEDIR\_YA signal and “This week” the PEDIR\_PRONTO ones. Each card carries the name, the signal, the SKU, the reason, the supplier, the quantity and the “Approve” and “Reject” buttons.
10. “Why?” opens the card's breakdown: current coverage, forecasted daily demand, supplier lead time, service level, unit cost, MOQ, current stock and reorder point.
11. As soon as you approve the first line, the cart bar appears at the bottom with the number of approved products, the total, the margin the order protects and the “Download purchase order” button.
12. Further down are “Suggested purchases and transfers” (the optimiser's plan for the whole horizon), “Get ahead — upcoming demand peaks”, “Demand changes”, “System recommendations” and “Capital opportunities”.

#### WHAT EACH FIGURE MEANS

| Field                       | What it is                                                                                                                                                                                  |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Total SKUs monitored</b> | How many products the sales upload in use covers.                                                                                                                                           |
| <b>Risk today</b>           | How many products carry the PEDIR_YA signal. It shows “—” when no product has stock on file, because a zero then does not mean “no risk” but “we do not know”.                              |
| <b>This week</b>            | How many products carry the PEDIR_PRONTO signal.                                                                                                                                            |
| <b>Average accuracy</b>     | How close the forecast was to actual sales in testing, measured on data the model did not see during training. 85% or more is good; below 70% it is worth reviewing that product's history. |
| <b>Warehouse value</b>      | Current stock times unit cost, summed. It shows “—” if you have not recorded a cost for any product: the value is unknown, not zero.                                                        |
| <b>Why?</b>                 | Opens the card's breakdown with the six to eight values the recommendation was built on. All of them come computed from the server; the screen invents none of them.                        |
| <b>Current coverage</b>     | How long the stock you have lasts at the forecasted sales rate. The unit follows your update's period (days in a daily update).                                                             |

| Field                                                      | What it is                                                                                                                                                                                             |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Supplier lead time</b>                                  | Days between placing the order and it reaching your warehouse. If it carries the “estimated” tag, it is StockAI's assumption (15 days) because nobody has configured it yet.                           |
| <b>Service level</b>                                       | The probability you want to cover demand with during the lead time. If you have not configured it, StockAI uses 95% and marks it as estimated.                                                         |
| <b>Unit cost / MOQ</b>                                     | The cost you recorded for that product and the minimum order the supplier requires. If you did not provide them, they are marked as estimated (the default minimum order is 1).                        |
| <b>Reorder point</b>                                       | The stock level at which you must order so the goods arrive before you hit zero: demand during the lead time plus the safety buffer.                                                                   |
| <b>Order:</b>                                              | The suggested quantity. You can click the number and type another one; changing it marks the line as modified and puts it in the cart.                                                                 |
| <b>Supplier:</b>                                           | Dropdown to point that line at a different supplier before the order is generated. Changing it also marks the line as modified.                                                                        |
| <b>Approve / Reject / Undo / Restore</b>                   | Approve puts the line in the cart; Reject takes it out and records that you did not follow the recommendation; Undo and Restore reverse each of the two.                                               |
| <b>This order protects ... in sales with ... in margin</b> | Sales and margin of the approved lines that have both a sale price and a cost on file. Lines missing either are left out and reported separately, so the figure is neither inflated nor deflated.      |
| <b>Deliver to</b>                                          | The order's destination warehouse. Only appears if you have two or more warehouses.                                                                                                                    |
| <b>Download purchase order</b>                             | Downloads the order's CSV and, at the same time, records the order in StockAI so it shows up in Orders and its arrival can be logged.                                                                  |
| <b>Send to suppliers now</b>                               | Appears right after the order is generated. Sends the order by email or WhatsApp to every supplier that has contact details on their record.                                                           |
| <b>Suggested purchases and transfers</b>                   | The optimiser's plan: what to buy and what to move to cover your whole planning horizon at the lowest total cost. “Convert to PO” turns one line into a purchase order without going through the cart. |
| <b>Get ahead — upcoming demand peaks</b>                   | Peaks the forecast sees before the traffic light turns red, with the deadline to order based on the supplier's lead time.                                                                              |
| <b>Capital opportunities</b>                               | How much money you have tied up in products with excessive coverage, and which ones they are.                                                                                                          |
| <b>Last updated / Refresh data</b>                         | How long ago what you see was loaded, and the button to request it again.                                                                                                                              |

## HOW TO

### Generate today's purchase order

1. Go through the cards under “Urgent — act today” and “This week”. 2. On each one, adjust the quantity or the supplier if needed. 3. Press “Approve” on the ones you will order and “Reject” on the ones you will not. 4. Check the cart bar at the bottom: approved products, total and protected margin. 5. If you have several warehouses, pick one under “Deliver to”. 6. Press “Download purchase order”: the CSV downloads and the order is recorded in Orders.

### Change the quantity StockAI suggests

1. Click the number next to “Order:”. 2. Type the quantity you are going to order. 3. Press Enter or click outside the field. 4. The line is marked as modified and goes into the cart with your quantity.

### Send the order to the supplier

1. Generate the order with “Download purchase order”. 2. In the “Purchase order generated” panel, check which lines go to which supplier. 3. Press “Send to suppliers now”. 4. If a supplier is listed as skipped for missing contact details, use “Send to my WhatsApp” or “Copy message” and forward it yourself.

### Record the arrival of a late order

1. Find the “Did these orders arrive?” block near the top of the screen. 2. Press “Record arrival” on the supplier's line. 3. In the window that opens, type how much of each product arrived. 4. Press “Everything arrived” if the whole order came in, or “Save quantities” if it arrived partially.

### Understand why a product is recommended

1. On the product's card, press “Why?”. 2. Read the explanation sentence and go through the breakdown values. 3. Notice which ones carry the “estimated” tag: those are our assumptions, not your data. 4. If any of them is wrong, fix it in Inventory and reload this screen.

#### WORTH KNOWING

- “Download purchase order” does two things at once: it downloads the file and records the order. If the recording fails you will see an error notice: in that case you have the CSV but the order does NOT exist in StockAI, and you have to generate it again.
- “Suggested purchases and transfers” usually asks for more units than the cards above. That is not a contradiction: the cards answer “what do I order today” and the optimiser answers “how do I cover the whole planning horizon”.
- A “Risk today” of zero does not always mean you are safe. If your products have no stock on record, the indicator shows “—” and a note: no risk was detected because nothing was measured.
- With the viewer role you see every recommendation but cannot approve them: instead of the buttons you get “Your role cannot generate orders”.
- The “estimated” tag next to a number is not an error. It means StockAI chose that value because nobody configured it; as soon as you record yours, it stops appearing.

## WHAT IT IS FOR

This is the full list of your products with the stock traffic light. Here you check product by product how much coverage is left, how much should be ordered and where that number comes from; and here you fix the data everything else rests on: current stock, supplier, lead time, cost, sale price and minimum order.

## WALKING THE SCREEN

1. The header reads “Inventory” with the subtitle “Stock signal · Purchase recommendations”, and the data-freshness indicator on the right.
2. Next to it is the view switcher: Table, Simple, Provider, Update stock (only if your role can edit), Money not moving, Rising costs, Shrinking margin, Forecast in money and Cost of ignoring.
3. The toolbar holds the refresh button, the CSV import, “Template”, “Export PO”, “Export PO (edited)”, PDF, and the links to Impact, Suppliers and “Log stock-out”.
4. If some products were left out of the forecast, a notice lists them with the reason for each one.
5. Below that comes the plain-language situation line (“N product(s) will run out before your next order arrives...”) and, when relevant, the notice of how many SKUs have no stock on record.
6. The row of six cards — Total SKUs, Order NOW, Order soon, OK, Overstock and Inventory value — also works as a filter: click one and the table shows only that signal.

7. If you have two or more warehouses, the warehouse selector sits right below; picking one replaces the main table with that warehouse's traffic light.
8. The table's own bar has a search box for SKU, name or supplier, and on the right how many SKUs are left after the filter.
9. The table lists one product per row: Signal, SKU / Name, Stock, Trend, Coverage, Demand (LT), Qty to order, Lead time, MOQ, ABC-XYZ and Warehouse value.
10. The ► arrow at the start of the row opens “How this recommendation was calculated”: the subtraction step by step, from average daily sales down to the final quantity.
11. The icons at the end of the row open the scenario simulator (lead time, demand variation and extra stock) and the product editor, where you change name, category, stock, supplier, lead time, MOQ, cost, sale price and service level.
12. At the foot of the screen are “Events and seasons”, to record Black Friday or year-end with their multiplier, and the legend explaining the five signals.

#### WHAT EACH FIGURE MEANS

| Field                                             | What it is                                                                                                                                                                                                                                                             |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Signal</b>                                     | The product's traffic light, computed by comparing its coverage against its lead time: PEDIR_YA below half a lead time, PEDIR_PRONTO below 1.2 lead times, OK below 3, and SOBRESTOCK from 3 lead times up. No data appears when the stock or the forecast is missing. |
| <b>SKU / Name</b>                                 | The product code, the name you gave it and its supplier.                                                                                                                                                                                                               |
| <b>Stock</b>                                      | Units on hand today. It says “No record” when that figure was never loaded.                                                                                                                                                                                            |
| <b>Trend</b>                                      | A thumbnail of how your stock moved over the last 14 days.                                                                                                                                                                                                             |
| <b>Coverage</b>                                   | How long your current stock lasts at the forecasted rate. The header states the unit, which follows your update's period.                                                                                                                                              |
| <b>Demand (LT)</b>                                | How much you expect to sell while waiting for the order to arrive.                                                                                                                                                                                                     |
| <b>Qty to order</b>                               | What you should order today: demand over the lead time plus the safety buffer, minus current stock and minus what is already on the way; never below the MOQ. You can edit it by clicking the number.                                                                  |
| <b>Don't order / Not yet · once it drops to N</b> | What appears instead of a quantity when it is not time to order yet. “Not yet” states the stock level at which it will be.                                                                                                                                             |
| <b>Lead time</b>                                  | Days your supplier takes. It carries the “estimated” tag while it is StockAI's assumption (15 days); it becomes learned once you record 3 receptions from that supplier.                                                                                               |
| <b>MOQ</b>                                        | Minimum units per order. We never recommend less than that number; above it we ask for what you actually need (it is not a pack multiple).                                                                                                                             |
| <b>ABC-XYZ</b>                                    | A/B/C is revenue importance and X/Y/Z is how predictable demand is. AZ — high value and erratic demand — is the trickiest.                                                                                                                                             |
| <b>Warehouse value</b>                            | Current stock times unit cost. It only appears if you recorded the cost.                                                                                                                                                                                               |

| Field                                         | What it is                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>How this recommendation was calculated</b> | The breakdown the ► arrow opens: average daily sales × lead time days, + safety stock, – current stock, = before rounding, and the rounding up to the MOQ when it applies. Below it, when there is a prior value to compare against, “Why it changed” says whether the change since last time came from a new forecast update or from something that moved in your own business — your stock or your lead time. |
| <b>Scenario simulator</b>                     | Sliders for lead time, demand variation and extra stock that show how the recommended quantity would change. It saves nothing: it is for looking.                                                                                                                                                                                                                                                               |
| <b>Simple view</b>                            | The same information cut down to four columns — product, signal, qty to order and supplier — for a quick read.                                                                                                                                                                                                                                                                                                  |
| <b>Provider view</b>                          | Groups products by supplier, showing how many urgent and how many upcoming each one has.                                                                                                                                                                                                                                                                                                                        |
| <b>Update stock view</b>                      | An editable table of stock, lead time and supplier so you can fix many products in a row and save them at once. Only for roles that can edit.                                                                                                                                                                                                                                                                   |
| <b>Export PO / Export PO (edited)</b>         | The first downloads the order the server computes; the second downloads the order with the quantities you edited in the table. Both record the order in Orders.                                                                                                                                                                                                                                                 |
| <b>Template / CSV / PDF</b>                   | “Template” downloads an empty CSV with the right columns; the CSV button imports your inventory (sku, current_stock, lead_time_days); PDF downloads the whole traffic light as a report.                                                                                                                                                                                                                        |
| <b>Log stock-out</b>                          | Deducts units that left the warehouse for a reason other than a sale — breakage, expiry, self-consumption, gift or sample — and accumulates their cost in the shrinkage summary.                                                                                                                                                                                                                                |
| <b>Events and seasons</b>                     | High-demand seasons with a demand multiplier (×1.2 to ×3.0). As soon as you save the event it changes the quantity to order for the products it applies to — not just a simulator exercise. See “Events that move the recommendation” later in this chapter.                                                                                                                                                    |

## HOW TO

### Fix a product's stock

1. Find it by SKU or name in the search box. 2. Press the pencil icon at the end of the row. 3. Change “Current stock” and anything else that is wrong. 4. Press “Save”. 5. The signal and the quantity to order are recomputed with the new figure.

### Load your whole inventory at once

1. Press “Template” and open the file that downloads. 2. Fill in the sku, current\_stock and lead\_time\_days columns. 3. Press the CSV button and pick your file. 4. Check the notice telling you how many rows were imported out of how many.

### See where a suggested quantity comes from

1. Press the ► arrow at the start of the product's row. 2. Read the subtraction step by step. 3. Look at the origin of the lead time shown next to the lead-time days. 4. To try another scenario, open the simulator with the sliders icon.

## Log shrinkage

1. Press “Log stock-out” in the top bar. 2. Type the SKU and pick the product. 3. Enter how many units left and choose the reason. 4. Confirm: stock drops immediately and the cost is recorded.

### WORTH KNOWING

- “No data” is not a StockAI error: it is a product whose stock you never recorded. While it stays that way it is left out of the purchase recommendations, because how much to order depends on exactly how much you have left.
- A row can say “Order soon” and “Not yet” in the quantity at the same time. They do not contradict each other: the signal warns the buffer is thin, and the quantity says you are still above the reorder point.
- Two products with the same coverage can carry different signals. The traffic light compares coverage against each product's own lead time, so 10 days of stock are comfortable with a 5-day supplier and critical with a 30-day one.
- Editing the quantity directly in the table saves nothing on the product: that number is only used if you download “Export PO (edited)”.
- The “Update stock” view does not appear for the viewer role. It is an editor, not a view, and saving would be refused anyway.

# Money not moving

/inventario

## WHAT IT IS FOR

The list of products whose stock has gone a long time without falling, ordered by how much money they represent, the most expensive first. It is not the same as the SOBRESTOCK signal: that signal compares your coverage against the product's lead time, so a product can read “OK” or even “Order soon” on the traffic light and still be money that has not moved in months, if demand simply stalled without stock ever crossing the overstock threshold. This view needs no trained update and no forecast: it reads your stock's real history directly.

## WALKING THE SCREEN

1. Opens from the “Money not moving” view in the Inventory switcher.
2. At the top is a total in money — it only counts products with a cost on file — and a note of how many idle products have no cost and are left out of that total.
3. The table lists one product per row: name and SKU, supplier, current stock, what it is worth (or “No cost on file”), and how long it has gone without falling.
4. Priced products come first, most expensive to least; unpriced ones come last, ordered by how many days they have been still.
5. When the recorded history is not long enough to have ever seen the stock fall, the day count is not an exact date: it reads “at least N days” — a floor, not a closed measurement.
6. With an active update, every row also carries its current signal, so you can compare the two readings without leaving the screen; with none active, the signal reads “No active session”.

## WHAT EACH FIGURE MEANS

| Field                | What it is                                                                                                                                                    |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SKU / Name</b>    | The product, its supplier and its category.                                                                                                                   |
| <b>Current stock</b> | Units you hold today.                                                                                                                                         |
| <b>Worth</b>         | Current stock times unit cost. If the product has no cost on file, it does not show a zero: it reads “No cost on file — we don't know what it's worth”.       |
| <b>Still since</b>   | The days since that product's stock last fell. When the recorded history is short, the figure carries “at least”, because it is a floor, not an exact date.   |
| <b>Signal</b>        | The product's current traffic-light signal, if you have an active update. It gates nothing on this list: a product can appear here under any signal, or none. |

## HOW TO

### Find where most of your money is sitting still

1. Open the “Money not moving” view in Inventory.
2. Check the total at the top: it only adds up products with a cost on file.
3. Scroll down the table: it is already ordered from most to least money.
4. If the product you care about says “No cost on file”, add its cost on the product card so it enters the total.

## WORTH KNOWING

- This view replaces the old “Dead stock” one. That view priced a product with no cost on file at zero and sent it to the bottom of the list, as if no money were at risk; it was retired so this question has one list.
- A product with no cost on file never counts as zero. If it did, it would read as “no money at risk here”, which is the opposite of what missing the data means: it is shown apart and counted apart instead.
- “At least N days” is not the same as “N days”. It appears when the recorded history does not reach far enough back to have ever seen the stock fall, and it is a floor on what is known, not an exact measurement.
- You do not need a trained update to see this list: it builds itself from your stock's real history, so a product you never put through a forecast can still show up here.

# Rising costs and shrinking margin

/inventario

## WHAT IT IS FOR

Two views that read the same source: what you actually paid on every reception of goods, not what the supplier's card claims. "Rising costs" ranks your suppliers by how much they have raised their prices; "Shrinking margin" ranks your products by how many points their margin lost. Both exist so a cost increase does not slip past you for lack of checking every product one by one.

## WALKING THE SCREEN

1. Open from the "Rising costs" and "Shrinking margin" views in the Inventory switcher.
2. Both read only receptions that actually arrived: a quoted or rejected order is not evidence of what you paid.
3. "Rising costs" groups by supplier: each row carries how much they raised overall and, inside it, the products that pushed that increase the most.
4. "Shrinking margin" ranks your products from the one that lost the most margin to the one that lost the least, with the before and after margin side by side.
5. Above "Shrinking margin" there is a control for the minimum margin points lost you want to see; half a point by default, so the list is not full of noise.
6. A fixed notice explains the limit both views share: StockAI stores only your CURRENT sale price, never a price history, so the "before" margin is built from today's price and the cost from back then — it can never blame a price cut, only a cost increase.

## WHAT EACH FIGURE MEANS

| Field                             | What it is                                                                                                                                                                                                                   |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Increase</b>                   | The percentage that supplier, or that product, rose in price over the window you are looking at, comparing the first recorded reception with the most recent one.                                                            |
| <b>Products that rose most</b>    | Within a supplier, the ones that pushed that increase the hardest.                                                                                                                                                           |
| <b>Margin before / Margin now</b> | The margin with the cost from the first recorded reception and with the most recent one, both using your CURRENT sale price. It is not a real historical margin: it is what would have happened had the price never changed. |
| <b>Points lost</b>                | The gap between the before and the now margin, in percentage points. Only products that lost at least the minimum you set above make the list.                                                                               |
| <b>You are selling below cost</b> | A notice that appears when the current margin is negative: cost has already overtaken the sale price.                                                                                                                        |

## HOW TO

### See which supplier has raised your prices the most

1. Open the "Rising costs" view.
2. The table is already ordered by the supplier that rose the most.
3. Open their row to see which products drove that increase.
4. If you are going to renegotiate, those are the products to start with.

### Find the product whose margin is slipping away

1. Open the “Shrinking margin” view. 2. Adjust the minimum points if the list is too long or too short. 3. Compare “Margin before” with “Margin now” on the row you care about. 4. If the current margin is negative, the row says so explicitly: you are selling below cost.

#### WORTH KNOWING

- Both views need at least two recorded receptions of that product or supplier within the window. With only one there is nothing to compare against, and the product is left out instead of shown with an invented change.
- “Shrinking margin” never says you cut the price, even though that would also explain a lower margin. StockAI does not store your past prices, only your past costs, so it can only blame cost — never price, because it has no way to prove it.
- A product with no sale price on file, or without enough cost history, is left out of “Shrinking margin” and counted separately, not silently dropped.
- The margin you see here can come out negative, and is shown as such: the screen does not clip it to zero to look better.

# Cost of ignoring

/inventario

## WHAT IT IS FOR

The record of what StockAI recommended each day and what happened afterwards. For every product that carried a PEDIR\_YA or PEDIR\_PRONTO signal, it says whether you ended up ordering it, whether you likely ran out of stock for not ordering it, or whether there is no way to tell from what is on record — and that third answer is not a zero: it is that the evidence to claim anything is missing.

## WALKING THE SCREEN

1. Opens from the “Cost of ignoring” view in the Inventory switcher.
2. Lists one product per row with the outcome of every alert it carried: ordered in time, likely stockout, or cannot tell.
3. “Likely stockout” only appears when StockAI actually saw your stock hit zero after the alert, never because it assumed it would.
4. When the stockout was still open at the end of the window you are looking at, the screen flags it as a floor: what you lost so far, not what you will lose in total.
5. “Cannot tell” appears when you neither generated the order in time nor saw stock hit zero: there is no evidence that ignoring the alert cost you anything, and none for the opposite either.
6. Lost units and lost value use your average daily demand and your CURRENT sale price; if either is missing, the row says so instead of guessing a number.

## WHAT EACH FIGURE MEANS

| Field                  | What it is                                                                                                                                                        |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ordered in time</b> | You generated a purchase order for that product within the 14 days after the alert.                                                                               |
| <b>Likely stockout</b> | You did not order in time, and StockAI saw your stock hit zero afterwards. Lost units and lost value come computed, never as zero.                                |
| <b>Cannot tell</b>     | You did not order in time, but you also never saw stock hit zero. It is not that nothing happened: it is that there is no evidence to say so, nor to rule it out. |
| <b>Price unknown</b>   | Appears when the lost units are known but their value is not, because the product has no sale price on file.                                                      |

## HOW TO

### See what not ordering in time cost you

1. Open the “Cost of ignoring” view.
2. Look for the rows marked “Likely stockout”.
3. Check the lost units and lost value on each.
4. If one says it is a floor, the stockout was still open at the end of the window: the real figure is at least that much.

## WORTH KNOWING

- “Cannot tell” is not a disguised way of saying zero. It is the honest answer when there is neither an order nor an observed stockout: the evidence is missing, in either direction.

- Lost value is revenue, not margin: units times today's sale price, not what you would actually have earned.
- This screen prices a past stockout with today's sale price, because StockAI stores no price history. Inventing what the price was back then would be exactly the kind of number this screen exists to avoid.
- A product with no average daily demand on record cannot have lost units computed, and the row says so instead of showing a zero.

# Events that move the recommendation

/inventario

## WHAT IT IS FOR

Declaring a high season — Easter, Black Friday, your own campaign date — is not an exercise: as soon as you save it, it changes what StockAI tells you to order, every day, until the date passes. The multiplier you type does not apply in full overnight: it is scaled by how much of your lead time falls inside the event's dates.

## WALKING THE SCREEN

1. Declared at the foot of Inventory, under “Events and seasons”: name, start date, end date and a demand multiplier, with an optional SKU or category.
2. As soon as you save the event, it starts moving the quantity to order for the products it applies to — not just the Scenario simulator's result.
3. The effect depends on how much of each product's lead time falls inside the event's dates: if your supplier takes 15 days and the event covers 4 of them, you do not get the full multiplier, only a fraction of it.
4. For example: a  $\times 1.8$  event covering 4 of a product's 15 lead-time days does not multiply its demand by 1.8, but by roughly 1.21 — the share of the delivery window the event actually reaches.
5. When a product's row changed because of an event, “Why it changed” tells you with the exact math: the event's name, its multiplier and how many of the lead-time days it applied over.
6. Several events that overlap on the same product combine with each other; they do not replace one another.

## WHAT EACH FIGURE MEANS

| Field                         | What it is                                                                                                                                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Demand multiplier</b>      | How much more you will sell during the event. $\times 1.8$ is 80% more. The screen classifies it from mild to peak depending on how high it is.                                                   |
| <b>Why it changed (event)</b> | When a row's change came from an event, the sentence carries its name, the multiplier and how many of the lead-time days it applied over — for example, “Easter: $\times 1.8$ over 4 of 15 days”. |

## HOW TO

### Get your inventory ready for a high season

1. Go to the foot of Inventory and open “Events and seasons”.
2. Create the event with its name, dates and the multiplier you expect.
3. Go back to the traffic light: the products it applies to already ask for more, in proportion to how much of the event falls inside their lead time.
4. To see the effect before saving it, use the Scenario simulator with a “Promotion” rule on the same dates.

## WORTH KNOWING

- The multiplier you type does not apply in full unless the event covers the product's whole lead time. The same one-week event moves a 30-day supplier's recommendation far less than a 5-day one's.

- This is different from the Scenario simulator: a simulated rule touches nothing until you delete it; an event saved under “Events and seasons” does change what you see on the traffic light every day, for as long as it runs.
- If two events overlap on the same product, their multipliers combine; the higher one does not simply win.

# The forecast in money

/inventario

## WHAT IT IS FOR

Multiplies what the forecast says you will sell by today's price and cost, to give a figure in money instead of just in units: how much you will sell, how much margin it will leave you, and which products carry that money.

## WALKING THE SCREEN

1. Opens from the "Forecast in money" view in the Inventory switcher, and needs an active update.
2. At the top are three figures: projected sales, projected margin and how many products made it into the count.
3. Below, a fixed notice reminds you the projection uses your CURRENT sale price, because StockAI stores no price history and does not know what the price will be in the future.
4. The table lists one product per row — units forecast, revenue, cost, margin and margin percentage — ordered from the one that contributes the most margin to the one that contributes the least.
5. A notice above the table says what percentage of the projected margin the top ten contributing products explain.
6. A product with no price or cost on file does not disappear from the table: it stays with that cell marked unknown, and is counted separately at the foot of the screen.

## WHAT EACH FIGURE MEANS

| Field                    | What it is                                                                                                         |
|--------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Projected sales</b>   | Units the forecast expects you to sell over the rest of the horizon, multiplied by today's sale price.             |
| <b>Projected margin</b>  | The same, but with each product's unit margin instead of the full price.                                           |
| <b>Products forecast</b> | How many products made it into the count. Ones with no forecast, price or cost do not, and are counted separately. |
| <b>Units forecast</b>    | The sum of that product's forecast over the rest of this update's horizon, never negative.                         |
| <b>Margin / Margin %</b> | Same rule as the rest of the app: if the price or the cost is missing, the cell says it is unknown, never a zero.  |

## HOW TO

### See which products carry your future money

1. Open the "Forecast in money" view.
2. Read the line above the table: it tells you what share of the margin the top ten explain.
3. Check those ten products first: they are the ones you can least afford to run out of.

## WORTH KNOWING

- The figure uses TODAY's price and cost, not a future one. If you are about to raise a price, or your supplier is about to raise a cost, this screen does not know it yet.

- A product with no price or no cost is not dropped: it is counted separately so the total does not look complete when it is not.
- The margin can come out negative, and is shown as such, with no clipping to zero.

## WHAT IT IS FOR

This is where everything you have already ordered lives. Every order you generated is recorded with what you bought, from whom and when; from this screen you send it to the supplier and log the arrival of the goods. Logging the arrival is what updates your stock and what teaches StockAI how long each supplier really takes.

## WALKING THE SCREEN

1. The header reads “Orders” with the subtitle “Generated orders and reception tracking”.
2. On the right sit the “N awaiting reception” counter and the “New order” button, which opens the manual order form.
3. If you have two or more warehouses, two tabs appear below: “Purchase orders” and “Transfers”.
4. Before the table come the supplier warnings: those with no email or WhatsApp on file that have open orders, and those running later than their own history.
5. If you have never generated an order, instead of the table you get a welcome screen with the “Go to the Purchasing Panel” button.
6. The table lists one order per row, newest first, with its number, date, number of SKUs, urgent, upcoming, units and total value.
7. The last column is the reception one: a status badge and, beside it, the “Log arrival”, “Send order”, “Send to my WhatsApp”, “Open in WhatsApp” and “Copy message” buttons.
8. “Log arrival” opens a window with the order's lines: for each product you see what was ordered, what was received before, and you type what is arriving now.

9. That window closes with “Save quantities”, if part of it arrived, or with “Everything arrived”, if the whole order came in.
10. “Send order” first shows you which suppliers it will be sent to and which will be skipped for missing contact details, and only then asks for confirmation.
11. “Send to my WhatsApp”, “Open in WhatsApp” and “Copy message” hand the order's text to you so you can forward it yourself; they do not depend on the supplier being configured.
12. “New order” opens a form where you pick the supplier and the destination warehouse and type the lines by hand: SKU, quantity and unit cost. No forecast required.

#### WHAT EACH FIGURE MEANS

| Field                                                              | What it is                                                                                                                                                                                |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>N awaiting reception</b>                                        | How many orders are still waiting for goods. It counts the ones on the way, the partial ones and the ones marked “Did not arrive”.                                                        |
| <b>Order</b>                                                       | The purchase order's number, exactly as assigned when it was generated.                                                                                                                   |
| <b>Date &amp; time</b>                                             | When the order was generated.                                                                                                                                                             |
| <b>SKUs in order</b>                                               | How many distinct products the order carries.                                                                                                                                             |
| <b>Urgent</b>                                                      | How many of its lines carried the PEDIR_YA signal when it was generated.                                                                                                                  |
| <b>Upcoming</b>                                                    | How many of its lines carried the PEDIR_PRONTO signal.                                                                                                                                    |
| <b>Total units</b>                                                 | The sum of units ordered across the whole order.                                                                                                                                          |
| <b>Total value</b>                                                 | The sum of quantity times unit cost. It shows “—” if the lines carried no cost.                                                                                                           |
| <b>Reception: On the way / Partial / Received / Did not arrive</b> | The state of the goods. “On the way” is also the state of an order nothing was ever logged against: the absence of a record is not proof the shipment arrived.                            |
| <b>Log arrival</b>                                                 | Opens the reception window. It appears while the order is on the way or partial.                                                                                                          |
| <b>Ordered / Received before / Arriving now</b>                    | The three columns of the reception window: what you ordered, what you had already logged and what you are receiving right now. The field comes pre-filled with what is still outstanding. |
| <b>Save quantities / Everything arrived</b>                        | The first records exactly what you typed line by line; the second marks the whole order as received without typing anything.                                                              |
| <b>Send order</b>                                                  | Sends the order by email or WhatsApp to the suppliers on its lines. Before sending it shows you who will receive it and who will be skipped.                                              |
| <b>Send to my WhatsApp / Open in WhatsApp / Copy message</b>       | These hand the order's text to you: to your WhatsApp, by opening WhatsApp with the message ready, or to the clipboard.                                                                    |
| <b>New order</b>                                                   | The manual order form: supplier, destination warehouse and one line per product with SKU, quantity and an optional unit cost.                                                             |
| <b>Transfers tab</b>                                               | Stock moves between your own warehouses, with their own send and reception cycle. Only appears with two or more warehouses.                                                               |

## HOW TO

### Record that the whole order arrived

1. Find the order in the table. 2. Press “Log arrival” in the reception column. 3. Check the lines are the right ones. 4. Press “Everything arrived”. 5. Each product's stock goes up and the order becomes “Received”.

### Record a partial arrival

1. Press “Log arrival” on the order. 2. Under “Arriving now”, type the units that actually arrived for each product. 3. Leave the ones that did not arrive at zero. 4. Press “Save quantities”. 5. The order stays “Partial” and keeps the button to log the rest when it comes in.

### Send an order to its suppliers

1. Press “Send order” on the order's row. 2. Read the summary: who it will be sent to and who will be skipped. 3. Press “Send” to confirm. 4. For the skipped suppliers, use “Copy message” and send it yourself.

### Create a manual order

1. Press “New order”. 2. Pick the supplier and, if you have several warehouses, the destination one. 3. Type the SKU, the quantity and — if you have it — the unit cost of each line. 4. Press “Add product” for the next lines. 5. Press “Create order”.

## WORTH KNOWING

- Marking “Did not arrive” does not close the order. It is a statement about a delivery that did not happen, not about a cancelled order, so the order keeps counting under “awaiting reception”.
- Logging the arrival is not paperwork: it is what raises your stock and what teaches StockAI that supplier's real lead time. After 3 recorded receptions StockAI replaces the configured lead time with the real average.
- “Send order” silently skips suppliers with no email or WhatsApp on their record; that is why the confirmation names them beforehand. For those, the way out is forwarding the message yourself.
- An order with no supplier assigned on any of its lines cannot be sent to anyone, and the confirmation tells you so before you try.
- With the viewer role you will not see “New order” and cannot log arrivals: both write business data.

# Messages

/mensajes

## WHAT IT IS FOR

One-to-one messaging between the people in your company, inside StockAI. It is for what happens around a purchasing decision — “already confirmed with the supplier”, “I halved that quantity” — without leaving for another app or losing the context.

## WALKING THE SCREEN

1. The left column starts with the “Messages” title and, on its right, how many people are on your team.
2. Below it is the people search box, always on screen and never shifting the list under your cursor as you use it.
3. Then comes the conversation list, most recent first: the person's initial, their name, the time of the last message and a preview of it.
4. When you have unread messages from someone, their row is shown in bold with a round counter on the right.
5. As soon as you type in the search box, a “Write to them for the first time” block also appears with the colleagues you have not talked to yet.
6. The right-hand area, until you pick someone, says “Pick a conversation”.
7. When you open a conversation, the person's name stays at the top; on narrow screens a back arrow to the list appears as well.
8. Messages read top to bottom: yours aligned right in the accent colour, theirs on the left, each one with its time.
9. A brand-new conversation opens with the line “This is the start of the conversation”.

10. At the bottom is the “Write a message...” field: Enter sends, and a message can be up to 4,000 characters.
11. Opening the conversation marks the messages sent to you as read and the counter disappears.
12. The application's top bar carries an envelope with your total unread count, which brings you back to this screen from anywhere.

#### WHAT EACH FIGURE MEANS

| Field                                            | What it is                                                                                                                                                                                                         |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>N on your team</b>                            | How many active people there are in your company that you can write to.                                                                                                                                            |
| <b>Search for a person...</b>                    | Filters your conversations and the rest of your colleagues at the same time, by name or by email.                                                                                                                  |
| <b>Conversation row</b>                          | Initial, name, time of the last message and its preview. If the last message is yours, the preview starts with “You:”.                                                                                             |
| <b>Unread counter</b>                            | The circle with a number on the right of the row: how many messages from that person you have not opened.                                                                                                          |
| <b>Write to them for the first time</b>          | A block that only appears while you are searching, listing the colleagues you have no conversation with yet.                                                                                                       |
| <b>Pick a conversation</b>                       | The right panel's initial state, before you have opened any thread.                                                                                                                                                |
| <b>This is the start of the conversation</b>     | What a freshly opened thread says when it has no messages yet.                                                                                                                                                     |
| <b>Write a message...</b>                        | The composer. Enter sends; the limit is 4,000 characters per message.                                                                                                                                              |
| <b>Send button</b>                               | The round button next to the field. It stays disabled while the message is empty or while it is being sent.                                                                                                        |
| <b>Top-bar envelope</b>                          | The global unread indicator; it shows “99+” past ninety-nine.                                                                                                                                                      |
| <b>Get a heads-up when someone writes to you</b> | A switch that lives in My account, not here. When it is on and your number is linked, you get a WhatsApp heads-up (or an SMS if WhatsApp is unavailable) if someone writes to you while you are away from StockAI. |

#### HOW TO

##### Write to someone for the first time

1. Type their name or email in the search box.
2. Find them under “Write to them for the first time”.
3. Click their name.
4. Type the message and press Enter.

##### Pick a conversation back up and mark it read

1. Look for the bold row with the unread counter.
2. Click it.
3. As it opens, the messages are marked as read and the counter disappears, along with the one on the envelope above.

##### Turn on the WhatsApp heads-up

1. Go to My account.
2. Link your WhatsApp number if you have not already.
3. Find “Team messages” and switch on “Get a heads-up when someone writes to you”.

#### WORTH KNOWING

- There are no groups and no channels: only one-person-to-one-person conversations, always within your own company.
- The list of colleagues you have not talked to only appears while you are typing in the search box. Without searching, the column shows just your conversations.
- The screen refreshes itself — the list every 15 seconds and the open thread every 5 — so a new message can take a few seconds to show up. There is no “typing...” and no read receipt for the sender.
- The WhatsApp heads-up is off by default and needs your number linked in My account. It also only fires when you are away from the conversation: if you have just read that person, you are not notified again.
- Users with the viewer role can send and receive messages too. The boundary here is the company, not the role.

# Your data

StockAI guesses nothing: everything you see in the traffic light comes from four screens you fill in yourself. Under "My sales" you upload the history the demand is computed from; under "Set up my inventory" you say how much you hold, what it costs you and how long it takes to arrive; under "Suppliers" you record who you buy from; and the "Supplier scorecard" compares what each supplier promises with what they actually deliver. While any of those is missing, StockAI says so on screen instead of quietly assuming it.

## My sales

/ventas

The screenshot shows the StockAI application interface. On the left is a dark sidebar with a menu. The main content area is titled 'My sales' and 'Demo StockAI | Day'. At the top right, it shows '12:56 PM' and some icons. Below the title bar, there are two tabs: 'Upload sales' (active) and 'Data sources'. The main heading is 'Upload your sales file' with a subtitle 'From zero to inventory traffic-light in under 5 minutes'. A progress bar at the top shows three steps: 1. Upload your sales (active), 2. Confirm columns, and 3. The system learns. The main form area contains the following sections:

- Upload your sales**: A note says 'We need your sales history. The file must have at least: **date, product and quantity sold.**'
- Give it a name (optional)**: A text input field with 'July sales' entered.
- How far ahead do you want to plan?**: Three buttons: '4 weeks' (selected), '8 weeks', and '6 months'.
- Plan detail level**: Four buttons: 'Auto (recommended)' (selected), 'Daily', 'Weekly', and 'Monthly'.
- Which country do you sell in?**: A dropdown menu with 'Colombia' selected.
- A note: 'We use it for public holidays: they are among the days that move sales the most, and every country has its own.'
- Three buttons at the bottom: 'Upload a new file' (highlighted), 'Use a file you already uploaded', and 'Repeat a previous upload'.

The sidebar menu includes sections for OPERATIONS (Purchasing Panel, Orders, Messages), DATA (My sales), PURCHASING (Inventory, Set up inventory, Suppliers), ANALYSIS (Forecasts, Impact, History, What happened, AI Assistant, Scenarios), and SYSTEM (Users, My account, Automation, Installation, API). The bottom of the sidebar shows 'Demo StockAI Administrator' and 'v0.1.0'.

### WHAT IT IS FOR

This is the product's front door. Here you upload your sales history, tell StockAI which column is which, and start the run that produces the per-product forecast. Everything else — the traffic light, the purchase orders, the scorecard — rests on what comes in through this screen.

### WALKING THE SCREEN

1. The screen opens on the first of three steps, shown along the top: "Upload your sales", "Confirm columns" and "The system learns".
2. Before you touch the file you fill in the plan: "Give it a name (optional)", "How far ahead do you want to plan?" with the options 4 weeks, 8 weeks and 6 months, and "Plan detail level" with Auto (recommended), Daily, Weekly and Monthly.

3. The last plan control is "Which country do you sell in?": it decides whose public holidays the model learns from, offers twelve countries, and comes preset to Colombia.
4. You drag your file onto the dashed box or click to browse; the box itself states "Accepted formats: CSV, Excel (.xlsx, .xls)".
5. If you have uploaded before, two more tabs appear next to "Upload a new file": "Use a file you already uploaded" and "Repeat a previous upload", which reuses that run's columns as well.
6. When the file is a CSV, StockAI checks it on your own machine before uploading and lists the problems with their row number, alongside a downloadable template.
7. With the file loaded you move on to "Confirm your columns": fifteen fields, three of them required and marked with a red star, where you pick which column of your file each one is.
8. Below the selectors there is a "Preview of your data:" with the first five columns and three rows, so you can check we read what you thought.
9. If the file holds something that would change the forecast without saying so, the block "There is something you have to decide first" appears with one question per finding, and the continue button stays dead until you answer them all.
10. Pressing "This looks good, continue →" starts the third step, with a bar moving through stages — "Learning from your history...", "Measuring how accurate it turned out..." — and when the daily view finishes it drops you straight on the purchasing screen.

#### WHAT EACH FIGURE MEANS

| Field                                     | What it is                                                                                                                               |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Give it a name (optional)</b>          | What this upload will be called in your history. It only helps you recognise it later; you can leave it empty.                           |
| <b>How far ahead do you want to plan?</b> | The forecast horizon in calendar days: 4 weeks is 28 days, 8 weeks is 56 and 6 months is 180.                                            |
| <b>Plan detail level</b>                  | Whether the plan is computed by day, week or month. "Auto (recommended)" lets StockAI decide from the shape of your file.                |
| <b>Which country do you sell in?</b>      | The holiday calendar the model learns from. Twelve countries are offered; leave it alone and Colombia is used.                           |
| <b>SKU / Product ★</b>                    | Required. The column identifying each product.                                                                                           |
| <b>Date ★</b>                             | Required. The column holding the date of each sale.                                                                                      |
| <b>Demand ★</b>                           | Required. The column with units sold — units, not money.                                                                                 |
| <b>Inventory</b>                          | Optional. Without it, a day with no sales cannot be told apart from a day with nothing on the shelf, and the forecast runs conservative. |
| <b>Lead time (days)</b>                   | Optional. If your file has no such column, the screen shows "Default: 15" — the fifteen days StockAI assumes.                            |
| <b>Preview of your data:</b>              | The first three rows of the first five columns, exactly as StockAI read them.                                                            |

#### HOW TO

### Upload your first sales file

1. Pick the horizon and the detail level, and change the country if you do not sell in Colombia.
2. Drag the CSV or Excel file onto the dashed box.
3. Read any row-level problems reported and fix the file if needed.
4. On step 2, confirm the three required columns and whichever optional ones you have.
5. Check the preview to make sure the columns landed where they belong.
6. Press "This looks good, continue →" and wait without closing the tab.

### Re-run the numbers on last month's file

1. On step 1, open the "Repeat a previous upload" tab.
2. Change the horizon or the detail level above to whatever you want to try.
3. Press "Repeat" on the upload you want to reuse: the same file and the same columns are carried over.
4. Confirm on step 2 and continue.

### Answer a data-check question

1. Read the finding's title, for example "We cannot tell whether your dates are day/month or month/day".
2. Compare the two options: each states what it does and what it costs you if you get it wrong.
3. Pick the one that matches your file; the one marked "recommended" is only a suggestion.
4. Once no question is left unanswered, the continue button switches on by itself.

#### WORTH KNOWING

- A product with fewer than 20 periods of history is not flagged with a warning: it is dropped before training. It gets no forecast and never appears in the traffic light, which is why the options that delete rows warn you how many products could fall below that minimum.
- On the free plan the file cannot exceed 25 MB and the catalogue is capped at 100 products; the paid plan raises the file to 2000 MB and removes the product cap.
- There is no "continue anyway". If the data check finds something with no possible fix, the only way out is correcting the column mapping above or uploading a different file.
- The holiday country starts on Colombia because that is what every upload silently used before this control existed. If you sell elsewhere, change it before uploading: it applies to that run, not retroactively.
- If your last finished upload used columns that still exist in the new file, StockAI reuses them and says so at the top. If any went missing, it names which ones and proposes the mapping from scratch again.

# Set up my inventory

/configurar-inventario

## WHAT IT IS FOR

StockAI already knows how much you will sell; this screen is where you tell it what to compare those sales against. It offers two routes to the same place: upload the file your system already exports, or fill in by hand only the products that carry your money. Both write to the same place and move the same bar.

## WALKING THE SCREEN

1. Under the title "Set up my inventory" a box states the rule: without stock or cost the product does not appear in the traffic light, and without a lead time it does appear — but planned on the 15 days StockAI assumes.
2. The first panel is "Or upload your system's file": CSV or Excel exactly as your system exports it, with no header editing.
3. You press "Choose file" and StockAI reads it immediately; for a CSV it checks the file on your machine first and names the row and the column of every problem.
4. Below, "This is how we read your columns" appears with one dropdown per field; change whichever is wrong, and anything left on "Do not import" stays out.
5. The summary tells you "Rows ready to import", "Rows with problems left out" and "Rows with no product code, skipped", with concrete examples such as "Row 214 (SKU-001): "N/A"".
6. You confirm with "Import" — the button carries the count in brackets — and when it finishes the screen says how many products came in and how many rows were left out.
7. The second panel, "Start with these", ranks your products by the money they move, not alphabetically and not by row order.

8. The bar at the top reads "X% of this month's purchase already configured" and underneath clarifies "The bar measures money, not rows", with the count of finished products over the total.

9. Each row shows the projected sales, what replacing them is worth, how much it weighs inside the month, the cumulative share, and a "Missing" column naming exactly which datum you do not have.

10. At the end of each row there are three boxes — Stock, Cost and Lead time (days) — and a "Save" button that confirms with the word "Saved".

### WHAT EACH FIGURE MEANS

| Field                   | What it is                                                                                                                       |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Current stock</b>    | How many units you physically hold today, not counting anything in transit.                                                      |
| <b>Cost</b>             | What YOU pay your supplier per unit — not the price you sell it at.                                                              |
| <b>Lead time (days)</b> | How many days pass between placing the order with your supplier and the goods being in your warehouse.                           |
| <b>Minimum order</b>    | The smallest quantity that supplier accepts per order, if your file carries it.                                                  |
| <b>Supplier</b>         | Who you buy that product from. It is what lets the order be grouped and, later, the supplier be measured.                        |
| <b>Projected sales</b>  | How many units we expect you to sell in the period, from your own history. It is a forecast, not a target.                       |
| <b>Worth</b>            | What replacing those sales will cost you: projected units times what you pay per unit. This is the figure the list is ranked by. |
| <b>Cumulative</b>       | Counting this product and everything above it, how much of your purchase for the period you have covered.                        |
| <b>Missing</b>          | What we still do not know about that product: stock, cost, lead time, price or supplier.                                         |

### HOW TO

#### Import stock from your system's file

1. Under "Or upload your system's file", press "Choose file" and pick your ERP export. 2. Check "This is how we read your columns" and fix any wrong assignment. 3. Set "Do not import" on the columns you do not want to bring in. 4. Look at the count of ready rows and of rows being left out. 5. Press "Import" and wait for the message with the total of products imported.

#### Reach 80% of your purchase without configuring the whole catalogue

1. Scroll down to the "Start with these" panel. 2. Follow the "Cumulative" column from the top down. 3. Fill in Stock, Cost and Lead time (days) on each row and press "Save". 4. Stop when the cumulative reaches 80%: the rest barely move money.

#### Fix a product whose "Missing" says cost

1. Find the row under "Start with these" and read what is missing. 2. Type into the "Cost" box what you pay your supplier per unit. 3. Press "Save" and wait for it to read "Saved". 4. Use "Refresh" to see the bar recomputed with that row now complete.

### WORTH KNOWING

- A product with no stock or no cost does not enter the traffic light, not even in green: it simply does not appear. Without a lead time it does appear, but planned on an assumed 15 days, so a supplier who takes 45 will be flagged to you too late.
- If a product appears more than once in the file, the last row wins. Rows with negative stock or cost are left out.
- The screen invents no zeros. If you save a row without entering the stock of a product that has no inventory recorded yet, it asks you for it: an invented zero is indistinguishable from a counted one and would turn a full warehouse red.
- Until you have given any cost or price, the list is ranked by volume and says so: "You have not given us costs or prices yet, so we rank by volume". Upload costs and it ranks by money again.
- The "Start with these" panel needs a forecast to prioritise with. If you have not uploaded sales yet, it shows a notice and sends you to do that first.

/proveedores

## WHAT IT IS FOR

## WALKING THE SCREEN

- StockAI · Your data

8. The "Learning" column states where each supplier stands: "No deliveries from this supplier recorded yet...", "n of 3 deliveries recorded...", "Learned from n deliveries: X days on average...", or the case where the recorded deliveries say nothing.
9. The tag icon at the end of the row expands that supplier's "Price breaks", with SKU, Min. quantity, Unit price and Notes.
10. The other two icons edit and delete the card; deleting asks for confirmation and warns that the action is irreversible.

#### WHAT EACH FIGURE MEANS

| Field                                           | What it is                                                                                                                                      |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>                                     | The only required field. It is the key that ties products, receptions and the scorecard together, and it is matched ignoring capitalisation.    |
| <b>Email (to send PO)</b>                       | The address purchase orders go out to from StockAI.                                                                                             |
| <b>Phone</b>                                    | The supplier's phone contact. Shown in the table next to the WhatsApp number.                                                                   |
| <b>WhatsApp</b>                                 | The number notices and orders can be sent to over WhatsApp.                                                                                     |
| <b>Payment terms</b>                            | How many days they give you to pay. It feeds the cash calendar, which estimates how much falls due each week.                                   |
| <b>Lead time (days)</b>                         | Days it takes to deliver to you from when you place the order. Applies to every one of their products without its own.                          |
| <b>Variability (days)</b>                       | How much that time can vary. If it says 15 days but sometimes arrives in 18, put 3. More variability means more safety stock.                   |
| <b>Notes</b>                                    | Special conditions, contact, remarks. Free text for you.                                                                                        |
| <b>Learning</b>                                 | A read-only column: how many of their deliveries you have recorded, and whether that is enough for StockAI to replace the configured lead time. |
| <b>Price breaks: Min. quantity / Unit price</b> | From that quantity on, each unit costs that price. Used to suggest when it is worth ordering more.                                              |

#### HOW TO

##### Register a supplier so you can send them orders

1. Press "Add supplier".
2. Type the name exactly as you use it on your products.
3. Fill in the email: with no email and no WhatsApp, sending orders skips them.
4. Set the lead time and the variability to what that supplier promises you.
5. Pick the payment terms and press "Create supplier".

##### Load a volume price break

1. On the supplier's row, press the tag icon to expand "Price breaks".
2. Type the SKU the scale applies to.
3. Enter the minimum quantity from which the price drops and the unit price at that quantity.
4. Press "Add tier" and repeat for each rung of the scale.

## Get StockAI to learn a supplier's real lead time

1. Record the arrival of every purchase order as you receive it. 2. Come back to this screen and read the "Learning" column. 3. Once it holds 3 recorded deliveries the text changes to "Learned from n deliveries", and that becomes the number we plan with. 4. If the learned figure differs a lot from what the supplier promises, correct their card too, so the scorecard measures them against a real promise.

### WORTH KNOWING

- StockAI does not replace the lead time you configured with the learned one until it has 3 recorded receptions from that supplier. With a single one, a freak delivery — a public holiday, a strike, a stranded truck — would rewrite the lead time for all their products.
- If every recorded delivery arrived the same day it was ordered, the observed average is 0 and says nothing about the supplier. StockAI declares it unusable, says so in the "Learning" column, and keeps using the lead time you configured.
- Payment terms are text that gets interpreted for the cash calendar. It understands "contado", "contra entrega", "anticipo", "prepago" and "COD" as 0 days; "N meses" as N times 30; "quincenal" as 15; and the first number in things like "30 días" or "net 30".
- What is NOT understood stays as an unknown term, reported as such rather than filled with an invented number: instalment schedules like "2x30" or "30/60/90", ranges like "30-45 días", and free text like "a convenir".
- The supplier's lead time governs all of their products that have none of their own; whatever you type on a product card always beats the supplier's value.

## WHAT IT IS FOR

## WALKING THE SCREEN

- ## WHAT EACH FIGURE MEANS

StockAI · Your data

| Field                  | What it is                                                                                                                                                    |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Receptions</b>      | How many of their arrivals you have recorded. It is the sample size behind everything else on the row.                                                        |
| <b>Real lead time</b>  | The range of days observed between order and arrival, from the minimum to the maximum.                                                                        |
| <b>Declared</b>        | The lead time on the supplier's card. It shows a dash if nobody ever filled it in, so they are not scored against a promise they never made.                  |
| <b>Trend</b>           | Whether their recent lead time stepped outside their own normal range. Shows the days of drift, "Stable", or "Not yet" when there is nothing to compare with. |
| <b>% On time</b>       | Share of deliveries whose real lead time was at or below the declared one. Blank when no lead time is declared.                                               |
| <b>% Fill rate</b>     | How much of what you ordered actually arrived, capped at 100%.                                                                                                |
| <b>Purchased value</b> | What you have bought from them, summing the lines that do carry a unit cost.                                                                                  |
| <b>Last reception</b>  | The date of the most recent arrival you recorded from that supplier.                                                                                          |

## HOW TO

### Compare what a supplier promises with what they deliver

1. Find their row and read "Declared" — what their card claims.
2. Compare it with "Real lead time", the range you have actually seen.
3. Read "% On time" to see how often they meet that promise.
4. If the real figure sits consistently above the declared one, correct the lead time on their card under Suppliers.

### Understand why a row says "Inconclusive"

1. Hover the text to read the full explanation.
2. It means every recorded delivery arrived the same day it was ordered.
3. Check whether you recorded the right arrival date when receiving those orders.
4. While it stays that way, StockAI plans with the lead time you configured, not with a zero.

### Fill the scorecard when it is empty

1. Read which of the two empty states you got: no receptions, or receptions with no supplier.
2. If it is the first, record the arrival of a purchase order from the history.
3. If it is the second, set the supplier on each product.
4. Come back to the scorecard: it fills up with the next arrivals you record.

## WORTH KNOWING

- The "Trend" column needs at least 6 receptions before it says anything: 2 in the recent window and 4 in the historical baseline. With fewer it shows "Not yet" rather than calling "Stable" a lead time nobody has seen vary.
- The fill rate is capped at 100%. A supplier who ships 120 against an order of 100 filled the order and also left you 20 units nobody asked for: that is a stock problem, not a merit.
- "Purchased value" is never a zero for lack of costs. If no line carried a unit cost it shows a dash, and if only some did it shows "≥" in front of the amount to warn you it is a floor, not the total.

- "Declared" is blank when nobody filled the lead time in on the supplier's card, and "% On time" goes with it. That is deliberate: the 15 days StockAI assumes are not a promise from the supplier and cannot be held against them.
- StockAI is stricter about accusing than about adjusting: 3 receptions are enough to learn a lead time, but 6 are required before a supplier is flagged for running late. Accusing costs more than adjusting.

# Analysis

These six screens are the ones that explain the reasoning behind every purchase decision. Here you see what StockAI projects for each product, how that product behaves in your own history, what would happen if the assumptions changed, what you have done with the recommendations, and what the AI can tell you about all of it. None of them generates a purchase order: they are for understanding before you buy, and the rest of the app takes care of the buying.

## Forecast by product

/pronosticos

### WHAT IT IS FOR

This is the screen where you see, product by product, what you sold and what StockAI expects you to sell. It brings together the historical curve, the forecast with its uncertainty range, the table of models that competed for that SKU, and the quality of its data. Everything the app decides afterwards — the signal, the reorder point, the quantity to order — comes from the model that wins here.

### WALKING THE SCREEN

1. Top left is the title “Predictions” with the number of SKUs in the selected update; on the right are “Export All SKUs”, “Compare”, the update selector and “Refresh”.
2. StockAI selects the active planning update on its own when the screen opens, and falls back to the most recent completed update when none is resolved.

3. The left column lists your products, with the “Search SKUs...” box above and pagination below; each card shows the SKU, a thumbnail of its series and its signal.
4. When you click a product, the header of the right-hand panel shows the SKU, its series type, how many rows of history it has, its quality percentage, its “Accuracy” and its signal.
5. Below that are three tabs by default — “Forecast”, “How it sells” and “Inventory” — and a “Show technical detail” switch that adds “Metrics” and “Quality” when you turn it on.
6. With technical detail off, the stats strip only carries “Average sales”, “Sales range” and “Reliability”: what you need to decide whether to trust the curve, with no model named.
7. In “Forecast”, the toolbar lets you change the “Granularity” (D, W, M, Q, Y) and the “Chart” (Line or Bar); the “Model” chips for comparing curves only appear once technical detail is on.
8. The “Likely range” button turns the uncertainty cloud on and off; it is drawn as three nested rings: “Wide range”, “Likely range” and “Middle zone”. It does not depend on technical detail: it is always there.
9. The “Model” chips, once technical detail is on, are multi-select: the first one you pick drives the axes and the statistics, and the rest are overlaid as lines in another colour so you can compare.
10. With technical detail on, the stats strip adds variability, historical points, forecast steps, “Chosen model's WAPE” and “Best model”, and the “Metrics” and “Quality” tabs appear.
11. The “Metrics” tab opens the table of every model that ran on that SKU, ordered by “Cost”, best first, with the “BEST” badge on the winner.
12. At the foot of the “Inventory” tab, the panel “What buying this way would have done” replays your purchasing policy over sales that already happened and compares it against ordering the same as last time.

#### WHAT EACH FIGURE MEANS

| Field                        | What it is                                                                                                                                                                                                                                                                                |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Show technical detail</b> | The switch that separates what you need to decide a purchase from what an analyst builds. Off — the state the screen opens in — you see the curve, what you normally sell and how much to trust the forecast. On, it adds the models that competed, their metrics and the data quality.   |
| <b>Reliability</b>           | High, Medium or Low: how solid the evidence behind the forecast is, computed from your data quality. Not the same as “Accuracy” — that measures how close the model came; “Reliability” measures how firm the ground it was computed on is. Always shown, even with technical detail off. |
| <b>Sales range</b>           | The minimum and maximum you actually sold, not a prediction: a quick read on how uneven the product is from one period to the next, without opening the “How it sells” tab. Also always shown.                                                                                            |
| <b>Accuracy</b>              | One minus the WAPE of the model chosen for that product, as a percentage. It is hidden when the best model's error is exactly zero, because that means there was no sale to get right.                                                                                                    |
| <b>Chosen model's WAPE</b>   | The WAPE of the model StockAI actually used for that product — not the lowest WAPE in the table. WAPE is the sum of absolute errors divided by total real demand.                                                                                                                         |

| Field              | What it is                                                                                                                                                                                     |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Best model</b>  | The SKU's winning model, baselines excluded. It is shown as “Model 1” ... “Model 9”: the algorithm's name changes no purchasing decision, and the numbering is the same everywhere in the app. |
| <b>Cost</b>        | What getting it wrong would cost with that model, counting a shortfall three times as expensive as a surplus. This is the column the winning model is picked by.                               |
| <b>MAE</b>         | Mean absolute error, in units of the product.                                                                                                                                                  |
| <b>RMSE</b>        | Like MAE, but squaring the errors: it punishes isolated large misses more.                                                                                                                     |
| <b>Bias</b>        | Mean signed error. Positive means the model forecasts too high; negative, too low.                                                                                                             |
| <b>Folds</b>       | How many walk-forward validation splits were used to measure that model.                                                                                                                       |
| <b>Type</b>        | Where the row comes from: a trained model or a reference. The references — “Reference (last value)”, “Reference (season)” and “Reference (average)” — are the bar to clear, not candidates.    |
| <b>Freq / View</b> | At the foot of the chart: the original frequency of your data and the level you are currently viewing the series at.                                                                           |

## HOW TO

### Compare two models on the same product

1. Pick the product in the left-hand list. 2. Turn on “Show technical detail” at the top right. 3. Stay on the “Forecast” tab. 4. Under “Model”, click a second chip: its forecast is drawn on top in another colour. 5. Turn off “Likely range” if the cloud gets in the way; it is only drawn with a single model selected. 6. Open “Metrics” to see which of the two has the lower “Cost”.

### Take the forecast into Excel

1. Select the product and the granularity you want. 2. Open the “Export” menu in the chart toolbar. 3. Choose “Excel (.xlsx)” for that SKU, or “CSV — chart data” if you only want the series. 4. For the whole catalog at once, use “Export All SKUs” at the top: it produces one file with a sheet per product.

### Check whether a retrain improved things

1. Press “Compare” in the top bar. 2. Pick the other update in “Comparing with:”. 3. Pick the SKU in the selector that appears beside it. 4. The screen splits in two: update A on top, B below, with the same product in both.

## WORTH KNOWING

- The metrics table is ordered by “Cost”, not by WAPE, so the model carrying the “BEST” badge may not be the one with the lowest WAPE. That is deliberate: running out costs more than having spare, and that is the comparison you buy on.
- References never win. They are in the table so you can see how far off forecasting “the same as last time” would be, but StockAI does not buy from them and they never get the “BEST” badge.
- Models are named “Model 1” through “Model 9”. Nine trained models compete, plus three references and the “Combined model”, which is the blend of the numbered ones.

- “Likely range” can only be turned on with a single model selected, and some models stored no quantiles: in that case the button stays off and “(no range)” appears beside it.
- Not every model runs on every product. StockAI assigns each SKU the models that suit its series type, always within the ones you chose when training, so two products from the same update can show different model lists.
- “Reliability” does not say whether the forecast was right: it says how solid the data it was computed on is. A product can have high “Accuracy” in testing and low “Reliability” if its history is short or irregular — the two are worth reading together.

# How it sells

/pronosticos

## WHAT IT IS FOR

The “How it sells” tab looks only at your history: no model is involved and nothing here is a prediction. It answers three business questions: whether the product is really growing or just repeating its pattern, which days or months it sells most on, and how uneven it is from one period to the next.

## WALKING THE SCREEN

1. You get here from the “How it sells” tab on the forecasts screen, with a product already selected.
2. The first block, “Is it really growing?”, draws two lines: the faint one is your sales as they happened and the thick one is the same sales with the usual ups and downs taken out.
3. If the thick line climbs, the growth is real; if it stays flat, what you were seeing was the pattern repeating.
4. Under the chart, one sentence says what percentage of the product's movement the pattern (weekly or yearly) explains and what percentage the trend explains; what is missing from a hundred is variation that does not repeat.
5. When the product has too little history to separate the two, that block draws nothing and instead says how many periods are needed and how many there are.
6. The second block averages your sales “By day” of the week or “By month”, depending on the chip you pick, and under each bar says how many periods it rests on.
7. The third block, “How much you sell per day / week / month”, splits your periods into ranges and counts how many times you landed in each, with a marker on the “Average”.

8. The tail on the right of that spread is the peak your stock has to absorb; that is the reading that justifies safety stock.

#### WHAT EACH FIGURE MEANS

| Field                             | What it is                                                                                                                                                                                              |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Actual sales</b>               | The series exactly as it is in your history, untouched.                                                                                                                                                 |
| <b>Trend</b>                      | The same series with the repeating component taken out.                                                                                                                                                 |
| <b>Weekly / yearly pattern</b>    | What percentage of the product's movement the repeating cycle explains.                                                                                                                                 |
| <b>Trend (percentage)</b>         | What percentage of the movement the underlying rise or fall explains. Whatever is left over up to a hundred is variation that does not repeat.                                                          |
| <b>Average by day of the week</b> | The average of what you sold each Monday, each Tuesday, and so on. It is an average, never a sum: a day with more records would look taller for a reason that has nothing to do with how much it sells. |
| <b>Average by month</b>           | The same, by calendar month. Useful for anticipating your strong months.                                                                                                                                |
| <b>Average</b>                    | The vertical marker on the histogram in the last block, placed at the average value of a period.                                                                                                        |

#### HOW TO

##### Decide which day to take delivery on

1. Open "How it sells" with the product selected.
2. In the second block pick the "By day" chip.
3. Read which days come out highest: those are the days the product has to be on the shelf.
4. Schedule the reception one or two days before that peak.

##### Tell real growth from seasonality

1. Open "How it sells".
2. Look at whether the thick line in "Is it really growing?" climbs or stays flat.
3. Read the sentence below it: if the pattern explains much more than the trend, what went up was the season.
4. If the block says history is too short, there is no answer yet; do not infer one from the chart above.

#### WORTH KNOWING

- Nothing on this tab is a forecast. These are averages of what you already sold, and the screen itself says so under each chart.
- The average by day of the week needs at least 8 weeks of history and sales on at least 5 distinct days. If you loaded your sales by week or by month, they cannot be split by day and the screen says so.
- The average by month needs at least 12 months of history; with less, comparing months compares incomplete seasons.
- Columns resting on fewer than 3 records are hidden, and the screen says how many it hid. A bar held up by two data points is noise drawn as a pattern.

# Scenario simulator

/escenarios

## WHAT IT IS FOR

The simulator answers “what if...?” without touching anything. You assemble a list of rules — more demand, a promotion, a late supplier, a different service level — and StockAI re-runs exactly the same signal calculation with those assumptions, then shows you the current plan and the scenario side by side.

## WALKING THE SCREEN

1. Top right you pick the “Forecast session” you want to simulate on; only finished sessions appear.
2. The left column is the builder: “Scenario rules”, which opens with one “Demand change” rule already in place.
3. Every rule starts with a type selector, and beside it one line explains what that type does.
4. There are four types: “Demand change”, “Promotion”, “Supplier delay” and “Safety stock”.
5. The fields change with the type: the first two ask for a multiplier and, optionally, a SKU or a category and a date range; the delay asks for days and an optional supplier; safety stock asks for a service level.
6. “Add rule” appends another line; the x on the right removes it.
7. “Simulate” runs the scenario and fills the right-hand column; from then on the button reads “Simulate again”.
8. Top right, “Current plan vs scenario” compares six figures — units to order, purchase value, SKUs to order, PEDIR\_YA SKUs, PEDIR\_PRONTO SKUs and overstocked SKUs — each with its difference.

9. Below it, “Most affected products” lists the SKUs whose signal or quantity changed, sorted by the size of the change, with the before and after of each.

10. If the scenario is worth keeping, give it a name under “Save scenario”: it lands in “Saved scenarios” and runs again from “Load”.

#### WHAT EACH FIGURE MEANS

| Field                                       | What it is                                                                                                                                                       |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Multiplier</b>                           | How much forecast demand is multiplied by. 1.4 is selling 40 % more. Accepted between 0.01 and 10.                                                               |
| <b>SKU (optional) / Category (optional)</b> | Which products the rule applies to. You fill in one or the other, never both. Left empty, the rule applies to the whole portfolio.                               |
| <b>From / To</b>                            | The date range the rule acts in. On a “Promotion” they are required; on a “Demand change” they are optional.                                                     |
| <b>Extra days</b>                           | Days added to the lead time, between 0 and 365. They are added on top of the lead time the signal already plans that product on, not on top of some other value. |
| <b>Supplier (optional)</b>                  | Limits the delay to one supplier. Left empty, it delays them all.                                                                                                |
| <b>Service level</b>                        | How often you want demand covered during the lead time. The selector offers 90 %, 95 %, 97 % and 99 %.                                                           |
| <b>Current plan / Scenario / Difference</b> | The three columns of the comparison: your plan as it stands today, the same calculation with the rules applied, and the subtraction between them.                |
| <b>{n} series adjusted</b>                  | How many forecast series the demand rules reached. A rule with no SKU and no category reaches all of them.                                                       |
| <b>Signal</b>                               | In “Most affected products”, the signal before and after the rules, with an arrow between the two.                                                               |

#### HOW TO

##### Get ready for a high season

1. Pick the forecast session. 2. Keep the “Demand change” rule and raise the multiplier to what you expect to sell on top. 3. Leave SKU and category empty to apply it to everything, or type the seasonal category. 4. Press “Simulate”. 5. Read the “PEDIR\_YA SKUs” row of the comparison: that is how many products turn urgent at that demand.

##### Measure the damage of a late supplier

1. Change the rule type to “Supplier delay”. 2. Type the number of days late. 3. Type the supplier's name exactly as it appears in your data, or leave it empty for all of them. 4. Press “Simulate” and check “Most affected products”: the last column shows the lead time before and after.

##### Save and reuse a scenario

1. Build the rules and simulate until the result convinces you. 2. Type a name under “Save scenario” and press “Save”. 3. It appears under “Saved scenarios”. 4. To run it again, press “Load”: the rules return to the builder and the result is recomputed against today's data.

#### WORTH KNOWING

- Simulating changes nothing: it does not move your stock, does not generate purchase orders, does not retrain and does not modify the stored forecast. The result is computed and displayed, not saved.
- The scenario does not invent new maths. It uses the same signal calculation you see in Inventory, fed with the assumptions you typed; that is why the “Current plan” figures match that screen.
- A scenario takes up to 50 rules and is tied to one session. If you change session in the selector, the comparison on screen is cleared: it would be an old result under a new title.
- A rule targets a SKU or a category, never both. Typing into one of the fields clears the other on its own.
- Saving and deleting scenarios requires the analyst or admin role. A read-only user can simulate and load scenarios, but does not see the save block.

# Impact and ROI

/impacto

## WHAT IT IS FOR

“Impact & ROI” is the record of what you did with StockAI: how many orders you generated, how many urgent lines you ordered, how much purchasing value you handled and how closely you followed the recommendations. The screen is deliberately conservative: it does not estimate savings and does not count stockouts avoided, because neither can be measured from your data. Everything you see is a sum of records the app already wrote.

## WALKING THE SCREEN

1. First comes “Recap for <month>”, the tally of the month that just closed: the same one that reaches you by email on the first day of each month.
2. If you generated no order that month, the block does not show zeros: it says there is not enough history yet and names the month it is talking about.
3. Its tiles are purchase orders generated, adoption percentage, urgent lines you ordered, overstock reduction and managed purchases.
4. At the foot of the recap, “Where each number comes from” explains in one paragraph the origin of each figure and what it does not claim.
5. Below it, “Your history with StockAI” accumulates across all time: orders generated, since which date, how many days active, urgent lines ordered and the value of the purchases managed.
6. When no product carries a unit cost, that last figure is replaced by the total units ordered and it suggests loading costs.

7. “Confidence in recommendations” shows your adoption rate with a bar: how many of the lines you decided on you ended up ordering.

8. “Monthly evolution” is the table of the last six months with orders, urgent lines ordered, value managed, adoption percentage and overstock reduction.

9. At the end, a link takes you to the orders screen to record receptions, and “Why this matters” closes by explaining that these are records of what you did, not a measurement of what you avoided.

#### WHAT EACH FIGURE MEANS

| Field                                    | What it is                                                                                                                                                                           |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>purchase orders generated</b>         | How many orders you generated from StockAI. It is a count of records, not an estimate.                                                                                               |
| <b>days active</b>                       | Distinct calendar days on which you generated at least one order. It is not the time elapsed since the first one: someone who ordered twice a year apart has 2 days active, not 365. |
| <b>urgent lines you ordered</b>          | Lines flagged PEDIR_YA that you actually ordered. It counts lines, not distinct products, and it includes orders that have not arrived yet.                                          |
| <b>purchases managed with StockAI</b>    | Units ordered times their unit cost, taken from your own data. It only sums the lines that carry a recorded cost.                                                                    |
| <b>adoption rate</b>                     | Lines you approved or adjusted, divided by the lines you actually decided on. Recommendations you let pass untouched are on neither side.                                            |
| <b>Overstock reduction</b>               | The difference between the value of your overstocked inventory at the start of the month and at the start of the next. It is two measurements subtracted, not a model.               |
| <b>Not enough history yet</b>            | What the overstock column says when one of the two monthly measurements is missing.                                                                                                  |
| <b>Your overstock went up this month</b> | What that same column says when both measurements exist and overstock grew. That is a result, not missing data.                                                                      |
| <b>≥ in front of an amount</b>           | Only some of the ordered lines carried a unit cost, so the figure is a floor: the real value is higher.                                                                              |

#### HOW TO

##### See whether you are following the recommendations

1. Open Impact. 2. Find “Confidence in recommendations”. 3. Read the percentage and the sentence beside it: it says how many lines you followed out of how many you decided on. 4. If the dismissed count is high, review the lead times and service levels of those products before blaming the forecast.

##### Close the month with figures you can defend

1. Open Impact on the first day of the month. 2. Read “Recap for <previous month>”. 3. Copy only what the tile claims; if a number says “Not available”, say exactly that instead of writing a zero. 4. If you need the full money figure, load the unit cost of the products that lack one and look again.

#### WORTH KNOWING

- This screen never says “StockAI saved you this much”. It does not estimate savings or count stockouts avoided, because that would require knowing what would have happened had you not bought, and that is not in your data.
- The overstock reduction is not attributed to StockAI. Overstock also falls when you sell, record shrinkage, delete products or retrain; the screen says what moved, not who moved it.
- A number that cannot be computed appears as “Not available” with the reason, never as a zero. A zero would read as a result.
- “Urgent lines you ordered” sums lines: the same 30 urgent products ordered every month for a year add up to 360. It also does not check that the goods arrived.
- The adoption rate does not say what share of everything StockAI suggested you followed. Recommendations you never touched are not recorded anywhere, so they are on neither side of the division.

# AI Analyst

/asistente

## WHAT IT IS FOR

The AI Analyst is a chat that answers about your own data: model accuracy, the quality of your series, forecast trends and the state of your inventory. It keeps conversations, you can star them and search them later, and each user sees only their own. A conversation can hang off a forecast session, or stay on “— General —” for conceptual questions.

## WALKING THE SCREEN

1. The left column lists your chats, with “New Chat” at the top and a search box below.
2. Chats are grouped into “Favorites” and “Recent”; the star on each row moves it between groups and the bin deletes it, asking for confirmation first.
3. The title of a new chat is written by the AI itself from your first question.
4. Above the thread, the “Session:” selector decides which forecast session the context comes from; “— General —” switches that context off and leaves only conceptual and platform questions.
5. In an empty thread, StockAI offers “Suggested questions” so you can start with one click.
6. You type at the bottom and send with Enter; Shift+Enter inserts a line break.
7. Every answer carries a badge saying where it came from: “Your data”, “General answer”, “General”, “Off topic”, “No access” or “Error”.
8. The filter button beside the input opens “Data Sources” and lets you limit the context to data overview, model performance, per-product accuracy, inventory, data quality, model routing, configuration or forecast trends.

9. If the answer does not arrive in time or the service fails, your question stays in the thread with a message explaining what happened, so you can retry it without retyping.

#### WHAT EACH FIGURE MEANS

| Field                      | What it is                                                                                                                        |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Session:</b>            | The forecast session the chat's context comes from. It changes which training run the accuracy and the trends are about.          |
| <b>— General —</b>         | A chat with no session: the AI answers about forecasting concepts and about how the platform works, without looking at your data. |
| <b>Data Sources</b>        | The filter that limits which parts of the context the answer may look at. With no filter, the button reads “All sources”.         |
| <b>Your data</b>           | The badge on an answer built from your session and inventory context.                                                             |
| <b>General answer</b>      | The badge on an answer assembled from the session context, but without a prior semantic search.                                   |
| <b>Off topic</b>           | The question does not resemble anything in your data, and the AI says so instead of inventing an answer.                          |
| <b>Suggested questions</b> | The shortcuts that appear in an empty chat; clicking one sends it as a question.                                                  |

#### HOW TO

##### Ask about today's inventory

1. Open a new chat. 2. Type the question directly, for example which products are at risk. 3. Read the answer and check it against the Inventory screen: the assistant reads that same signal.

##### Understand why a product has low accuracy

1. Under “Session:” pick the session where that product was trained. 2. Ask about the SKU exactly as it appears in your data. 3. To narrow the answer, open the “Data Sources” filter and leave “Per-product accuracy” and “Data quality” ticked.

##### Find an old conversation

1. Type in the search box of the left column. 2. Or star the chats you will come back to: they stay at the top, under “Favorites”.

#### WORTH KNOWING

- Inventory answers always come from the signal of the active planning update, not from the session you picked in the chat. That is deliberate: inventory has exactly one answer in this product, and it is the one on the Inventory screen.
- The inventory context the AI receives is limited to the first 40 products. On a large catalog, the answer describes that slice and not the whole catalog.
- The AI only reads what the session and the inventory already computed. It does not run models, does not browse the internet and does not see your original files.
- Every answer is built from the last 6 messages of the thread. What you said much further up in a long conversation is no longer in the context.

- There is a limit of 20 messages per minute for the whole organization, and a question cannot exceed 4000 characters. The answer also has a time budget: if it runs out, the screen says so and keeps your question.

## /historial

## WHAT IT IS FOR

## WALKING THE SCREEN

- ## WHAT EACH FIGURE MEANS

| Field                    | What it is                                                                                       |
|--------------------------|--------------------------------------------------------------------------------------------------|
| <b>Name</b>              | The name of the update. You can change it whenever you like; it exists only so you recognise it. |
| <b>Status</b>            | Where it ended up: “Completed” has results, “Calculating” is in progress, “Failed” stopped.      |
| <b>File</b>              | The sales file that update came from.                                                            |
| <b>Created</b>           | The date it was created.                                                                         |
| <b>Plan through</b>      | How many periods ahead that run forecast.                                                        |
| <b>Detail</b>            | Whether the series was worked “Daily”, “Weekly” or “Monthly”.                                    |
| <b>SKUs</b>              | How many products went into that update.                                                         |
| <b>Technical detail:</b> | The exact reason for the failure, as the forecasting engine reported it.                         |

## HOW TO

### Go back to an earlier result

1. Open History. 2. Find the “Completed” row you want, by its name or its date. 3. Click anywhere on the row: the forecasts screen opens with that update selected.

### Give them names you will recognise later

1. Press the pencil on the row. 2. Type a name that says what is inside, for example the month or the warehouse. 3. Press Enter, or the green check. 4. Escape cancels without saving.

### Find out why an update failed

1. Look for the row with status “Failed”. 2. Read the text following “Technical detail:”. 3. If the message is about columns or dates, fix the file and upload it again. 4. If you do not understand it, pass it on verbatim to whoever supports you: that is what it is written for.

## WORTH KNOWING

- Deleting an update also deletes the demand projections that came out of it, and it cannot be undone.
- An update cannot be deleted while it is “Calculating”; the button stays off until it finishes.
- Renaming and deleting require the analyst or admin role. A read-only user sees the table and opens results, but does not see those buttons.
- The detail of a failure comes in English from the forecasting engine. That is not a missing translation: it is the exact technical message, and rewriting it would make diagnosis harder.

# Your account and the system

What you set up once and rarely touch again: who gets in, with which permissions, the currency your figures are shown in, and what runs on its own.

## Users

/usuarios

The screenshot shows the 'Users' management page in the StockAI application. The sidebar on the left contains navigation links for 'OPERATIONS' (Purchasing Panel, Orders, Messages), 'DATA' (My sales), and 'PURCHASING' (Inventory). The main content area is titled 'User Management > Demo StockAI > Day'. It features a 'Users' section with a sub-header '1 user in this workspace'. There are 'Refresh' and '+ Create user' buttons. Below this is a search bar 'Search by name or email...' and two filter dropdowns: 'All statuses' and 'All roles'. A table lists the users with columns: NAME / EMAIL, STATUS, ROLE, CREATED, LAST LOGIN, and ACTIONS. The table contains one row for 'Demo StockAI (you)' with email 'demo@faro.app', status 'Active' (indicated by a green badge), role 'Administrator', created date 'Sep 22, 2026', last login 'Sep 30, 2026', and an edit icon in the actions column.

| NAME / EMAIL                        | STATUS | ROLE          | CREATED      | LAST LOGIN   | ACTIONS |
|-------------------------------------|--------|---------------|--------------|--------------|---------|
| Demo StockAI (you)<br>demo@faro.app | Active | Administrator | Sep 22, 2026 | Sep 30, 2026 |         |

### WHAT IT IS FOR

This is where an administrator adds their team and decides what each person may do. It is the one screen in the product a non-administrator cannot even open: anyone without the role sees “You don’t have permission to view this page”.

### WALKING THE SCREEN

1. The header says how many users are in this workspace and carries two buttons: “Refresh”, which reloads the list, and “Create user”.
2. Creating a user asks for a full name (optional), an email address (required) and a role; the screen tells you that an account setup email with a verification link will be sent to them.
3. The table has six columns: Name / Email, Status, Role, Created, Last login and Actions, and your own row is marked “(you)”.
4. Status shows as a coloured badge — Active, Pending, Inactive or Suspended — and Role as Administrator, Analyst or Read only.
5. The chevron button at the end of each row switches the status between Active, Inactive and Suspended; it does not appear on your own row, because nobody can suspend themselves.
6. When somebody is “Pending” an envelope icon appears as well: it resends the verification email, and the button itself confirms whether it went out or failed.
7. The pencil icon opens “Edit user” to fix the name, the email or the role; changing the email forces re-verification.
8. The bin icon opens “Delete user?”, which reminds you that all their sessions, tokens and permissions will be removed and that this cannot be undone; that icon is also absent from your own row.
9. Above the table there is a search by name or email and two filters, “All statuses” and “All roles”, and the list pages 20 at a time with the “Showing X–Y of Z” count.

### WHAT EACH FIGURE MEANS

| Field                 | What it is                                                                                                                                                                                                                                   |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Administrator</b>  | Can do everything an analyst can and is additionally the only role that manages the team from this screen, changes the currency, the time zone and how often purchases are computed.                                                         |
| <b>Analyst</b>        | Works normally: uploads files, trains, edits inventory, records purchase orders, creates API keys and schedules recalculations. The one thing they cannot do is manage users.                                                                |
| <b>Read only</b>      | Sees the whole product and changes nothing. Any action that modifies data answers with a permission error and the state stays as it was: they cannot upload files, train, edit stock, record orders, create keys or schedule recalculations. |
| <b>Account status</b> | Active works normally; Pending has not opened the verification link yet; Inactive and Suspended cannot sign in.                                                                                                                              |

## HOW TO

### Add somebody from your team

1. Open Users and click "Create user".
2. Type their email and, if you want, their full name.
3. Choose the role: Analyst if they will buy or load data, Read only if they will only look.
4. Save: they receive a setup email with the verification link.
5. Until they open it they will show as "Pending"; if it never arrived, use the envelope icon to resend it.

### Cut off access for somebody who left

1. Find the person by name or email.
2. If it is temporary, open the status chevron and set them to "Inactive" or "Suspended".
3. If it is final, use the bin icon and confirm in "Delete user?".
4. Be clear that deleting removes their sessions, tokens and permissions and cannot be undone.
5. If that person had created API keys, revoke them separately in Automation: a key stays alive even after its creator is gone.

## WORTH KNOWING

- The free plan holds two users: you and one more. Trying to create a third opens "You reached your free plan limit", which explains that no feature is locked and gives you three ways to write to us.
- You cannot change your own status or delete yourself: neither control is drawn on your own row.
- What decides permissions is the role, not a list of per-person checkboxes. There are no individual permissions to configure.
- "Pending" does not mean something failed: it means that person has not opened the verification email yet. Resend it with the envelope icon before creating them a second account.
- Changing somebody's email sends them back to verification. Until they open the new link they cannot invite people or send notifications.

# My account

/mi-cuenta

## WHAT IT IS FOR

This is the settings screen, and it mixes two things worth keeping apart: what is yours — your name, your language, your theme, your password, your WhatsApp — and what belongs to the whole company — currency, time zone and how often purchases are computed, which only an administrator changes and which apply to everybody. The usage and limits panel lives here too.

## WALKING THE SCREEN

1. The left column is “User Profile”: the full name is edited with the pencil icon and saved right there; email, role and account status are shown but not editable.
2. The first card in the right column is “Usage and limits”, with the plan badge and one bar for every thing that can fill up: Products (SKUs), Users, Warehouses, Saved forecasts and API keys.
3. The bar changes colour as you approach — amber past 80 %, red at the ceiling — and the “I need more room” button opens the dialog to write to us: there is nothing to buy on the screen.
4. “Currency” decides which symbol your figures are shown in — inventory value, unit costs and purchase-order totals — and shows an example with the formatting applied.
5. “Time zone” is the one used to read the frequencies in Automation: schedule “every Monday at 6am” and it runs at 6am in that zone, and the card tells you what time it is there right now.
6. “App Settings” holds the language (Español / English) and the theme (Light / Dark); these are your own preferences, stored on your account, and they affect nobody else.
7. “How often your purchases are computed” only appears when your history affords more than one period, explains why the system chose the one in use, and lets you switch between Day, Week and Month.

8. “Security” changes the password in two steps: you type the new one (at least 8 characters), we email you a 6-digit code that expires in 10 minutes, and you confirm with it.
9. “WhatsApp” links and verifies your number with a code, and below it the direct-SMS toggle stays blocked until you have a verified number.
10. Further down, “Available Models” lists the platform’s forecasting models with their category and whether they are available or in beta.
11. At the bottom, “Activity Logs” shows what has been done in the account — action, resource, status and date — with a filter by action type and a “Load more” button that says how many records are left.

## WHAT EACH FIGURE MEANS

| Field                                        | What it is                                                                                                                                                          |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Full name</b>                             | The only editable part of your profile. Saved with the “Save Changes” button on that card.                                                                          |
| <b>Email address</b>                         | Shown, not edited here. An administrator changes it from Users, and the change forces re-verification.                                                              |
| <b>Role and Account status</b>               | Informational. The role is assigned by an administrator from Users.                                                                                                 |
| <b>Language and Theme</b>                    | Yours. Stored on your account, so they follow you to any browser you sign in from.                                                                                  |
| <b>Currency</b>                              | Company-wide, and only an administrator changes it. It changes the symbol; it does not convert amounts you already loaded.                                          |
| <b>Time zone</b>                             | Company-wide, and only an administrator changes it. It rules the hour at which scheduled recalculations run.                                                        |
| <b>How often your purchases are computed</b> | Day, Week or Month, for the whole account and only by an administrator. Only the periods your history affords are offered.                                          |
| <b>Usage and limits</b>                      | Five bars: Products (SKUs), Users, Warehouses, Saved forecasts and API keys. On the free plan those are 100, 2, 1, 3 and 1; on the full plan they read “Unlimited”. |
| <b>Security</b>                              | Password change with a 6-digit code emailed to you, valid for 10 minutes.                                                                                           |
| <b>WhatsApp</b>                              | Your verified number for receiving messages from StockAI. Without it the SMS toggle cannot be turned on.                                                            |

## HOW TO

### Change your password

1. Open My account and scroll to “Security”. 2. Click “Change password”. 3. Type the new password, at least 8 characters. 4. Press “Send code to email” and check your inbox. 5. Enter the 6-digit code before the 10 minutes run out and confirm the change.

### See how much room you have left and ask for more

1. Open My account and look at the “Usage and limits” card, top right. 2. Read each bar: it tells you how much of how much you have used. 3. If any is amber or red, click “I need more room”. 4. Choose how you would rather talk to us: WhatsApp, email, or the form in the same dialog. 5. Tell us how many products, warehouses and people you handle: that is what we need in order to raise your limits.

#### WORTH KNOWING

- Changing the currency only changes the symbol: it converts nothing. If your costs are in colones and you pick dollars, you will see colones with a dollar sign.
- The time zone does not change how your sales or forecasts are displayed. The only thing it decides is what hour the scheduled recalculations run at.
- Changing how often your purchases are computed is not a change of view: it changes the quantities we suggest you buy and what reaches you by email and WhatsApp every morning, and a product with little history can disappear from the daily calculation and still appear in the weekly one.
- The usage panel shows five limits, not every limit there is. The maximum file size (25 MB on the free plan) and the daily API call ceiling are counted separately.
- There is no purchase screen and no checkout. Moving to the full plan is a conversation with us, and the “I need more room” button is the entire commercial surface of the product.

# Automation

/automatizacion

## WHAT IT IS FOR

Two things that make StockAI work without anybody opening it: the keys another system uses to reach your data, and the schedule on which your forecasts recompute themselves. Only an administrator sees this entry in the menu.

## WALKING THE SCREEN

1. The screen has two tabs: “API Keys” and “Schedules”.
2. In API Keys, the first thing you read is the fact that matters: the key is shown once, when you create it, we do not store it anywhere, and if it is lost you create another and revoke the old one.
3. “Generate key” opens two fields: a name so you can recognise it later — for instance “ERP integration” — and “What the key can do”, with two options, “Read only” and “Read and write”.
4. Once created, a box appears with the full key, which starts with `sk_live_`, and a “Copy” button; that is your only chance to save it.
5. The table below lists your keys with Name, Created and Last used — which says “Never” if nobody has used it — and a “Revoke” button per row that asks for confirmation, because any apps using it will stop working.
6. In “Schedules” you first pick a session in the “Session:” dropdown; only sessions that finished training appear there.
7. “Frequency” offers six ready-made schedules and shows the matching cron expression in monospace underneath, so there is no doubt about what was saved.
8. The “Schedule enabled” checkbox keeps the schedule saved but switched off when you clear it, and the button saves or updates depending on whether that session already had one.
9. Once saved, the screen tells you “Next run:” with a date and time and states which time zone those hours are in: the one your company has configured in My account.
10. Above it sits “Already scheduled”, the list of everything armed across every session — with its frequency, whether it is paused, its next run and, if the last one failed, the error — and each line is a shortcut to edit that schedule.
11. Below that, “Recent scheduled runs” shows the real history: date, session and whether it finished, failed, is running, is queued or was cancelled.

## WHAT EACH FIGURE MEANS

| Field                        | What it is                                                                                                                                          |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Key name</b>              | Only so you recognise it in the list. Name it after the system that will use it.                                                                    |
| <b>What the key can do</b>   | “Read only” queries the traffic light and the forecasts. “Read and write” additionally uploads files, queues trainings and records purchase orders. |
| <b>Every Monday at 6am</b>   | Cron 0 6 * * 1.                                                                                                                                     |
| <b>Every day at midnight</b> | Cron 0 0 * * *.                                                                                                                                     |
| <b>Weekdays at 6am</b>       | Cron 0 6 * * 1-5.                                                                                                                                   |
| <b>Every Sunday at 8am</b>   | Cron 0 8 * * 0.                                                                                                                                     |
| <b>Every hour</b>            | Cron 0 * * * *.                                                                                                                                     |
| <b>First day of month</b>    | Cron 0 0 1 * *.                                                                                                                                     |
| <b>Schedule enabled</b>      | Clearing it keeps the saved schedule but fires nothing until you tick it again.                                                                     |

## HOW TO

### Create a key so your ERP can read the traffic light

1. Open Automation and stay on the “API Keys” tab.
2. Click “Generate key”.
3. Give it a name that says which system uses it, for example “ERP integration”.
4. Under “What the key can do” leave “Read only” if the ERP will only query.
5. Press “Create” and copy the key right then with the “Copy” button: it is never shown again.
6. Paste it into your system’s configuration and check in the table that the “Last used” column stops saying “Never”.

### Let your forecasts recompute themselves every week

1. First confirm in My account that the company time zone is yours.
2. Open Automation and go to “Schedules”.
3. Pick the session you want retrained in “Session:”.
4. Under “Frequency” choose “Every Monday at 6am”.
5. Leave “Schedule enabled” ticked and press “Save schedule”.
6. Check that it appears under “Already scheduled” with the next run at the hour you expected.

## WORTH KNOWING

- The key is shown once. If you close the box without copying it there is no way to recover it: you have to create another and revoke the old one.
- Revoking is immediate and warns nobody. Anything that was using that key stops working on its next call.
- The free plan holds a single API key, and every key allows 120 calls per minute and 500 per day; on the full plan the daily ceiling disappears.
- Schedule hours are read in your company’s time zone, not the server’s and not your browser’s. If that zone is wrong in My account, everything scheduled runs at the wrong hour.
- Only sessions that already finished training can be scheduled. If the dropdown says “No completed sessions”, train one first in My sales.

- Check “Already scheduled” and “Recent scheduled runs” from time to time: a schedule that has been failing for weeks looks just as calm in the menu, and that is where the error shows up.

# Public API

/api

**Public API**

Your system pushes the data and takes the decision, without anyone opening StockAI.

**THE BASE URL**

`http://localhost:5000/api/v1`

**Authentication**  
Bearer `sk_live_...`

**RATE LIMIT**  
120/min · 500/day on the free plan

Your API key: `sk_live_...` [Generate a key](#)

**ENDPOINTS**

- GET** `/planning`
- GET** `/data-sources`
- POST** `/data-sources/{source_id}/...`
- POST** `/sessions/{session_id}/...`
- GET** `/sessions/{session_id}/...`
- GET** `/inventory/status`
- GET** `/inventory/morning-brief...`
- POST** `/inventory/log-po`
- PUT** `/bcp`

**Authentication**  
Every call carries your key in the Authorization header. Writing requires a read-and-write key.

**Rate limits**  
120 calls per minute per key, on any plan. The free plan also caps a key at 500 calls per day; the full plan does not. Over the cap: 429 with Retry-After.

**The response envelope**  
Every response is wrapped: your payload is in data. Errors carry `error_code`. Branch on the code, never on the text.

**TRY IT**  
`GET /planning`  
Returns the active\_session\_id the other calls need. Ask for it every run: it changes when a new session trains.

**EXAMPLE**  
CURL  
`curl "$STOCKAI/planning" \`  
`-H "Authorization: Bearer $KEY"`

**TRY IT**  
`POST /data-sources`  
Lists your sources so you know which source\_id to replace.

## WHAT IT IS FOR

The API reference, and also a console: every endpoint can be run from the page itself with your own key. It exists so your system pushes the data and takes the decision without anyone opening StockAI. It is not administrators only: an analyst is usually the person who wires an integration.

## WALKING THE SCREEN

1. The header shows “The base URL” with the exact address your calls go to, /v1 included; the paths on the page are written without that prefix, and the base is the \$STOCKAI value in the examples.
2. Below it there is a “Your API key” field where you paste an `sk_live_` key: it lives only in that tab while you use it and is neither stored nor sent anywhere else.
3. If you do not have one yet, the “Generate a key” button takes you straight to Automation.
4. The endpoint list stays fixed on the left; on the right, each one with its method, its path and an explanation of what it is for in real work.
5. The ones that modify data carry the “Writes” badge, and their test fields come with an amber notice of the effect they will have.
6. On each endpoint, “Try it” runs the call for real against your account and returns the HTTP status, the duration in milliseconds and the response; “Example” gives you the same call written as a curl command to copy.
7. Before running a write, a confirmation names the concrete consequence — replacing your file, queueing a real training run, or recording a purchase order whose reception is then tracked.

8. The reference sections at the end explain three things: authentication, which goes in the Authorization header; the rate limits, 120 calls per minute and 500 per day on the free plan, with 429 and Retry-After once you go over; and the envelope, where your payload always comes in data and errors carry error\_code.
9. At the end, just before the closing note, there is a “Connect your assistant (MCP)” section: your installation’s MCP server URL, the five tools it offers and a curl to check that your key works. It is for when what you want is not a system running on a schedule, but to ask an AI assistant what to buy today.
10. The page closes with an explicit promise: these endpoints do not change path or shape without notice, and any other endpoint of the service is internal — reachable with your key, but with no commitment to keep it.

## WHAT EACH FIGURE MEANS

| Field                                          | What it is                                                                                                                                                                 |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GET /planning</b>                           | Returns the active_session_id the other calls need. Ask for it every run, because it changes when a new session trains.                                                    |
| <b>GET /data-sources</b>                       | Lists your sources so you know which source_id to replace.                                                                                                                 |
| <b>POST /data-sources/{source_id}/file</b>     | Writes. Uploads the export in place: the source keeps its id and column mapping. Accepts .csv, .xlsx, .xls, .parquet and .json.                                            |
| <b>POST /sessions/{session_id}/train</b>       | Writes. Queues a retrain. If the session already has a schedule, you do not need this call.                                                                                |
| <b>GET /sessions/{session_id}/train/status</b> | The state of the last training run: QUEUED, RUNNING, COMPLETED or FAILED.                                                                                                  |
| <b>GET /inventory/status</b>                   | Every product with its signal and recommended_qty. There is no pagination: filter with signal or supplier.                                                                 |
| <b>GET /inventory/morning-briefing</b>         | The same data ordered as a day of work, with the reason, the suggested supplier and the estimated value.                                                                   |
| <b>POST /inventory/log-po</b>                  | Writes. Records the purchase order. Without this call the order does not exist for StockAI and your suppliers’ real lead times are never learned.                          |
| <b>POST /mcp</b>                               | The MCP server, for an AI client. Five tools, all of them reads: the active run, the day of work, the stock signal per SKU, your data sources and a training run’s status. |

## HOW TO

### Try the API without writing a line of code

1. Create a “Read only” key in Automation and copy it.
2. Open the API screen and paste it into “Your API key”.
3. Pick GET /planning in the list on the left and press “Run”.
4. Copy the active\_session\_id from the response.
5. Open GET /inventory/morning-briefing and run it: it is the same day of work you see on the Purchasing Panel, in JSON.

## Connect your AI assistant (MCP)

1. Create a “Read only” key in Automation — it is enough for everything below. 2. If your AI client takes a URL, give it the one shown under “Connect your assistant (MCP)” on the API screen, with the Authorization: Bearer header and your key. 3. If it is a desktop client such as Claude Desktop, which speaks over stdin/stdout rather than HTTP, copy `mcp_server/stockai_mcp.py` from the repository and set `STOCKAI_URL` and `STOCKAI_API_KEY`; there is nothing to install. 4. Ask it “what should I buy today?”: the answer comes from the same day of work you see on the Purchasing Panel.

## Automate the whole cycle from your own system

1. Create a “Read and write” key. 2. On every run, call `GET /planning` first to get the `active_session_id`. 3. Upload the latest sales export with `POST /data-sources/{source_id}/file` over the source you already use. 4. Queue the recalculation with `POST /sessions/{session_id}/train`, or skip this step if that session already has a schedule armed. 5. Poll `GET /sessions/{session_id}/train/status` until it says `COMPLETED`. 6. Read `GET /inventory/status` and build your order from the signal and the recommended\_qty. 7. When the order actually goes out, record it with `POST /inventory/log-po`, including the lines you rejected.

### WORTH KNOWING

- There is no test environment. The “Run” button on this page acts on your real account: uploading a file replaces that source’s file, and recording an order makes it appear in Orders.
- Careful with `log-po`: if you send an empty body, or one without an items list, nothing empty gets recorded — an order is recorded containing EVERY `PEDIR_YA` and `PEDIR_PRONTO` product in that session.
- A “Read only” key cannot write. If your integration uploads files, trains or records orders, it needs a “Read and write” key.
- Branch on `error_code`, never on the error text: the text can change language or wording, the code does not.
- The `active_session_id` changes every time a new session trains. Hard-coding it in your integration is the easiest way to end up reading a stale forecast.
- Only these endpoints carry a stability commitment. Your key reaches others, but nobody promised to keep them as they are.
- Nothing writes over MCP, and that is not a limit of the role: even with a “Read and write” key, an AI client only reads. Uploading files, training and recording orders stay on the endpoints above, where a person triggers them and can see what happened.
- An AI key reads your stock, your costs and your supplier names. Treat it like any other credential, and revoke it from the same screen that created it once it is no longer used.

# Installation

/instalacion

## WHAT IT IS FOR

The list of services this StockAI has connected, which ones are on, and what stops working with the ones that are not. StockAI runs without any of them — the forecast, the traffic light and the purchase orders depend on nothing external — but the assistant, email, WhatsApp and document search do. When one of those “does not answer”, this is the screen that says why.

## WALKING THE SCREEN

1. It has two tabs, and they answer to two different people. “This installation” belongs to whoever administers the server; “My channels” belongs to your company.
2. On a freshly installed deployment nothing has to be configured before you can get in: if yours is the only company, the panel opens for you and the key that encrypts whatever you save is created on its own.
3. Each service is a card with its state: Ready, Not configured, Failing or Off.
4. A Not configured service is not an error: the card says in one sentence what is lost while it stays that way, and names the exact variable that is missing.
5. “Failing” means something different from “not configured”: the credential is there but the provider rejected it, could not be reached, or did not answer in time. That difference is what tells you whether the fix is a new key or a network problem.
6. The “Test connection” button asks the provider whether the credential works. It never emails or messages anybody to find out.
7. Every field says where the value in effect came from: the environment (the server’s .env file), this panel, or your company. What you save here wins over the file and takes effect

without a restart.

8. Fields marked “Environment only” are shown but not editable: the server reads them at boot, so changing them from a screen would not take effect until a restart.

9. A stored key cannot be read back: the panel shows at most its last four characters, enough to recognise which one you pasted. If you lost it, issue a new one at the provider.

10. “Back to the environment” deletes what this panel stored for that service and lets the server’s file rule again.

11. Under “My channels” you set the sender YOUR customers and suppliers see: your own email account and your own WhatsApp number. Anything left empty uses the installation’s.

### WHAT EACH FIGURE MEANS

| Field                    | What it is                                                                                                    |
|--------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>This installation</b> | Every service of the deployment. Only whoever administers the server opens it, not any company administrator. |
| <b>My channels</b>       | Your email sender and your WhatsApp number. The scope is your company and nothing else.                       |
| <b>Ready</b>             | It has what it needs to run.                                                                                  |
| <b>Not configured</b>    | A credential is missing. The card names which, and what is lost.                                              |
| <b>Failing</b>           | Configured, but the last test failed.                                                                         |
| <b>Off</b>               | A deployment switch deliberately set to false.                                                                |
| <b>In effect</b>         | Which layer supplies the value in use: your company, this panel, the environment, or the built-in default.    |
| <b>Test connection</b>   | Asks the provider whether the credential works. It messages nobody.                                           |

### HOW TO

#### Turn the AI assistant on

1. Open Installation and find the “Assistant (DeepSeek)” card. 2. If it says “Not configured”, the line below names the missing variable: DEEPSEEK\_API\_KEY. 3. Paste the key into that field and press “Save”. 4. Press “Test connection”: it should say it answers correctly. 5. Open the AI Assistant — the “unavailable” notice is gone and you can ask.

#### Send email from your own domain

1. Go to the “My channels” tab. 2. On the “Email” card, paste your Resend key, or fill in server, port, user and password if you prefer SMTP. 3. Put the sender your suppliers should see in EMAIL\_FROM. 4. Save, then press “Test connection”. 5. From then on your alerts and purchase orders leave with your identity, not the installation’s.

### WORTH KNOWING

- If you see “This account does not operate the installation”, you did nothing wrong: server configuration belongs to whoever administers it, and is decided by a server variable rather than by your company’s administrator role. Your own channels you can still configure, in the other tab.

- If yours is the only company on this installation, you administer it even though nobody named you — whoever installs it is whoever signs up. That access ends the moment a second company arrives, and the panel warns you at the top. Before inviting anybody, put your address in `INSTANCE_ADMIN_EMAILS` (in the server's `.env` file) and restart, or nobody will be able to open this tab again.
- If the panel says the installation generated its own encryption key, it works but it carries two consequences: back up the server's storage/ folder, because losing that file means re-entering every credential; and if you ever run a second process on another disk, copy that key into `INTEGRATIONS_SECRET_KEY` first, or each process will make its own and be unable to read what the other stored.
- Email counts as configured with a Resend key OR with an SMTP user and password; you do not need both. The card states both ways.
- Account email — verifying your address, resetting a password, inviting somebody — always leaves through the installation's transport, even when your company has its own. A customer must not send the message that grants access to an account.
- A service saying "Ready" means it has its credentials, not that the provider is healthy. That is what "Test connection" is for.
